THE case of Dr. Lachlan Grant, whose treatment at the hands of the directors of the Ballachulish Slate Quarries Company, Limited, has been made the subject of detailed comment in these columns on several occasions, has taken a step forward. A judgment of Lord Kyllachy, it will be remembered, recently held that in dismissing Dr. Grant from his position as medical officer to the Ballachulish Slate Quarries the directors of the company had acted within their rights, although the men and not the directors paid Dr. Grant's salary and although they thoroughly trusted him and desired his continuance in his post.[1] Against this judgment Dr. Grant has appealed to the Inner Division of the Court of Session, before which the case came on May 29th. Four judges were on the bench and it is understood that after a prolonged discussion the court was equally divided upon the point at issue—viz., whether the agreement under which Dr. Grant held his office could be terminated at the sole will of the directors. The court made *avizandum*, so that its ultimate decision may be delayed some time. In the meantime Colonel Malcolm of Poltalloch, chairman of the Ballachulish Slate Quarries Company, has been to Ballachulish, has met the quarriers, and has been subjected to a severe heckling. Colonel Malcolm read a written speech to the men in which he protested that the directors had acted throughout in the men's interests and that the manager was the men's best friend. The speech was received with ridicule by his audience It was openly stated that the manager had caballed against Dr. Grant whose services the men paid for and intended to retain. Colonel Malcolm then made the amazing statement, according to the *Highland News* of May 30th, that Dr. Grant was dismissed "in order to make a new agreement with him." Being expressly asked if he meant "in order to make a new agreement with Dr. Grant" or "in order to make a new agreement with a different medical man," the Laird of Poltalloch deliberately repeated that it was intended "to reappoint Dr. Grant, but on a different footing," and immediately afterwards admitted that weeks before Dr. Grant was dismissed negotiations had been entered into with another medical man. Colonel Malcolm must have more than military courage to make such admissions. Colonel Malcolm also said that Dr. Dunlop Anderson of Ardsheal, a neighbouring landowner, who has been mentioned in our columns as throughout a firm supporter of Dr. Grant, had privately written to him recanting his position. This, we are informed by Dr. Anderson, is absolutely untrue, and proceedings have been taken to contradict Colonel Malcolm publicly. In this distressing case one thing is most clear and most gratifying—it is the absolute loyalty of the quarriers to Dr. Grant. They will not allow their employers to jockey them out of their clear right to select the medical man whom they pay; nor do they intend to let Dr. Grant have put upon him the gross injustice and slur of a summary dismissal when he has always discharged his duties efficiently. Surely the directors of the Ballachulish Slate Quarries must recognise that they are dealing with determined and reasonable men who, whatever the law may say, have justice on their side. Peace can only be restored by the reconfirmation of Dr. Grant in his post as medical officer to the quarries. This, Colonel Malcolm has said publicly, was the original intention of the directors and as the statement requires a little confirmation why should not his colleagues support Colonel Malcolm's words at once in a practical way? To do so will be to own themselves defeated? No By such thoughtful action they will show that they have reconsidered a position which they took up in haste and upon information of a very doubtful kind. They will display the bravery that is not afraid to own an error of judgment and they will secure the respect of their men as well as their services—whereas now they enjoy neither.

TONSILLITIS.

TONSILLITIS is usually a more or less common disorder in London during the later spring months. This year sore-throats appear to have been even more prevalent than usual; indeed, many of the attacks have been very severe and accompanied by erythematous rashes and constitutional symptoms which have made the diagnosis between them and scarlet fever a matter of some difficulty. Inasmuch as the specific characteristics of scarlet fever are not infrequently masked by the concomitant symptoms due to poisoning with streptococci, this difficulty of diagnosis is hardly to be wondered at. It is abundantly evident that the condition of the wood pavements, the recent drought, and the high winds have acted in coöperation to load the lower strata of the metropolitan atmosphere with organic and infective matter of a highly dangerous character. Although it is obviously possible by a more careful watering of the streets and by improved methods of scavenging to minimise the dangers arising from dust, it is improbable that, as long as we depend on the energy of the horse for the purpose of vehicular traction in the streets, we shall be free from epidemics of tonsillitis during times of drought and high winds. After all there are advantages, direct and indirect, not only in motor-cars, but also in petrol, as a source of energy and as an antiseptic for the streets.

[1] THE LANCET, Jan. 24th, 1903, p. 249.

FICTITIOUS WINES: SOME INTERESTING RECIPES.

WE believe on the whole that the great bulk of the cheap wines sold to the British public by respectable merchants are genuine, in so far that they are real fermented grape-juice. This is, perhaps, more particularly so in regard to Bordeaux wines, though, doubtless, there are genuine light red wines imported as French wines which, however, have not been produced in France Resent this comparatively trifling form of fraud as we may, it is obviously not so wicked as having a wine thrust upon us which is not fermented juice at all. A short time ago a person somewhere on the banks of the Rhine was caught compounding a fluid which he bottled and described as "Niersteiner," which of course implied that it was the wholesome wine produced in a certain district famous for its light Rhine wine. As a matter of fact, the fermented juice of the grape proved to be the smallest item in the formula, the rest being made up of alcohol, water, and certain flavouring materials. In this country also there is no doubt that to a certain extent—but we think a limited extent—fictitious wine is made. Thus, in some evidence given before the Departmental Committee on Food Preservatives four years ago it was stated that somewhere on the banks of the Thames a preparation was made which was sold as "St. Julien." As there was no duty paid on this stuff it is not surprising that its price was not more than 6½d. a bottle and we daresay that that figure left a fairly respectable margin of profit to the manufacturer. Possibly this "wine" brought a much higher price when ultimately sold by the retailer to an individual customer. It would be interesting to discover the true composition of the claret commonly labeled "St. Julien" which is to be found at most public-houses or country inns, however remote they may be. As a rule there is nothing but the description "St. Julien" or perhaps "Medoc" on the label and there is certainly no evidence of *bona fides* on the cork. In this connexion we have recently come across some interesting recipes for making wines which are calculated to throw some light on the "wine" which is now and again met with. To make Bordeaux wine, for example, "it is best to use a light Hungarian red wine. Mix with 50 gallons one pint of kino, two to three ounces of sulphate of iron, dissolved in one quart of boiling water, and one wine-glassful of extract of orris root and a like quantity of raspberry extract." We may parenthetically remark that we have occasionally tasted cheap clarets having a flavour resembling that of orris root. For making Burgundy it is enjoined to "mix in a barrel 100 parts of white wine, ten of the juice of black cherries, six of crushed large raisins, six of pulverised cinnamon, half of pulverised crude tartar, and 50 of must concentrated by evaporation." The following formulæ are also suggested. "*Champagne liqueur.* Boil eight and three-quarter pounds of the finest loaf sugar with one gallon of water, add gradually while the water is boiling half gallon of alcohol of 90 per cent. and then filter the mixture." "The above liqueur is added to all the following compounds." (We reproduce them literally to show the disgraceful use made of the names of certain well-known champagne firms.) "*Chandon et Moet (Green Seal).* Mix the above liqueur with seven and a half gallons of white wine and one quart of Cognac." "*Louis Röderer (Green and Bronze Seal).* Mix the champagne liqueur with seven and a half gallons of white wine, one bottle of Cognac, and four drops of sulphuric ether dissolved in Cognac." "*Heidesick et Cie (Sealed with Tin-foil).* Mix the champagne liqueur with seven and a half gallons of white wine and three quarters of a pint of Cognac." The next one is very interesting. "*Lemberg Geldermann et Deittz (Sealed with Tin-foil).* Mix double the quantity of champagne liqueur with seven and a half gallons of white wine and three-quarters of a pint of Cognac in which two roots of celery carefully cleansed have been previously digested for four hours." Similar formulæ for other brands are given and directions are appended for making Madeira, Malaga, and port. In one of these (Malaga) "*essence de Goudron*" is employed. The champagne preparations "are corked with champagne corks and laid on their sides with their mouths sloping downwards. They are recorked the next day with the corking machine. The corks before using them must be laid in hot water, and before placing them in the machine moistened with sugar syrup, and as soon as driven into the bottles tied with cord and finally wired." Anything more brazen than this we can hardly imagine.

FRACTURE OF THE BASE OF THE SKULL WITH SPECIAL REFERENCE TO PROGNOSIS AND MENTAL SYMPTOMS.

AT the presidential address recently delivered before the New York Neurological Society and published in the *Medical News* of May 16th Dr. Pearce Bailey gave an account of his investigations upon the subject of fracture of the base of the skull with special reference to prognosis, mental symptoms, and medico-legal bearings. The symptoms of fracture of the base of the skull had been described by Hippocrates. Though the symptoms were the result of an extreme degree of violence they presented, adds Dr. Bailey, a certain consistency of type. The mortality was high and varied from 55 to 60 per cent. Thus, of 58 cases of fracture of the base of the skull collected by Heer in 1892–99 death occurred in 29 cases, a death-rate of 50 per cent. Van Nes records 82 cases with 39 deaths, while Phelps, in his work on Traumatic Injuries of the Brain (1897), collected 286 cases of fracture with 176 deaths, a mortality-rate of 61 per cent. Of 69 cases collected by Weir, Bull, and the writer himself 40 died as the result of fracture of the base of the skull, a proportion of 58 per cent. The symptoms observed, both focal and general, were fairly uniform. The focal symptoms included amblyopia and amaurosis, oculo-motor paralysis, and paralysis of the facial nerve. Loss of consciousness and coma were the chief general symptoms. "The majority of the patients are in a state of coma when first examined and a goodly proportion die within 24 hours of the injury." Pupillary inequality with dilatation on the side most injured is the commonest symptom. There is a want of parallelism in the optic axes and diplopia may be detected in the milder cases. Facial paralysis comes next in order of frequency. The lower facial branches are more liable to be affected than the upper, and the facial paralysis tends to persist when the oculo-pupillary disturbances have passed away. The trigeminal nerve is rarely if ever the seat of focal paralysis. Injuries of the middle ear are frequent, together with involvement of the auditory nerve and deafness, but the exact mode of involvement of the auditory nerve is difficult to determine. A frequent symptom is weakness of the legs, coupled often with slight rigidity of the affected parts. Occasionally there may be hemiplegia. The knee-jerks are frequently lost at first but later they return and may even be exaggerated. As regards mental symptoms, Dr. Bailey points out that a large proportion of patients who die never emerge from the coma immediately succeeding the injury. The most characteristic mental state is one of semi-coma or stupor with delirium The patient lies still, resents being disturbed, and if disturbed becomes restive and irritable. There is frequently developed a muttering hallucinatory delirium which may, especially in alcoholic subjects, require watching and mechanical restraint. Sudden impulses to get out of bed and to rush out of the room are very common Memory of events for an hour or for a day or two prior to the accident may be entirely lost. Dr. Bailey cites two cases in one of which the memory of events during the half-hour preceding a railway accident, and in the other of the incidents of four days preceding the fall from a horse, were abolished. The duration of serious mental symptoms is variable. Some patients emerge from the initial coma lucid in mind and free from any trace of mental affection. Others continue in a state of semi-coma and delirium for days and weeks and in a few cases cerebral and mental disturbances persist long after physical strength is regained. As regards prognosis the combined statistical records of Heer, van Nes, Phelps, and the writer give 494 cases with a mortality of 57 per cent. Death in the majority of instances is directly due to the injury, thus, 62 per cent. of the deaths occurred within 24 hours and 95 per cent. within five days. Those dying after longer periods developed either pneumonia or meningitis. As regards the ultimate prognosis with reference to mental life 15 out of 29 patients were traced by Dr. Bailey and their conditions were carefully studied. The following cases are extracted as typical instances. In Case 1 the patient was a boy aged seven years at the time of injury (April, 1901). He recovered in a few days At present (1903) he goes to school. "He is slightly more irritable and boisterous than formerly and often becomes uncontrollable." He has no fits. Case 4 was that of a boy aged five years at the time of the accident (September, 1901). He recovered but has ever since then been nervous, irritable, and subject to headaches He has no fainting or convulsive fits. Case 6 was a girl aged 13 years at the time of the injury (December, 1901) There are no untoward symptoms in this case. Case 8 was that of a man, aged 26 years, who had fractured the base of the skull in August, 1901. For 12 days he was in a state of semi-coma. He made an excellent recovery At present he has slight ptosis and excess of one knee-jerk. There is amnesia for the events of four days preceding the injury. He is free from headaches or fits and his character is unchanged. Two other cases cited by Dr. Bailey showed after recovery a greatly increased susceptibility to alcohol Insanity is rare, concludes Dr. Bailey, after fracture of the base of the skull as compared with fracture of the vault of the skull. The mental conditions occurring in the latter class of cases are proposed to be dealt with in a subsequent paper.

BATTERSEA BLUSTERINGS.

THE borough council of Battersea is a body in no need of advertisement but we may nevertheless call attention to its methods of pursuing the campaign against vaccination and incidentally express our sympathy with the unfortunate general practitioners whose lot happens to be cast in the district ruled by that corporation. Those, and they are probably many, who remember the council's attitude towards His Majesty the King at the time of the Coronation will be prepared to learn that it displays scant courtesy in its dealings with such comparatively humble persons as members of the medical profession. In connexion with an outbreak of small-pox which, we are not surprised to find, has occurred in Battersea, the local health committee reported recently that "cases have been traced to previous cases of the disease which have been treated by the medical practitioners in attendance as cases of disease other than small-pox." From the statement of the medical officer of health it appears that in one case a patient was kept under observation, though not isolated, for four days before it was decided that notification was necessary, while in another, which was described as "a very difficult case to diagnose," the true condition was not recognised for an even longer time. On the strength of these facts, at the meeting of the council on May 27th, several members insisted that the names of the medical men concerned should be published. Some of the reasons adduced in support of this proposition are worth recording. One gentleman declared that "he had no compunction for the doctors; they had none for the anti-vaccinators." Another "hoped that they would take the reasonable step of publicity, so that they might have a reasonable hope that these offences would not be repeated." A third instanced the depravity of his own medical adviser, against whom he launched the crushing indictment: "He's never been paid yet." Undue harshness was deprecated by the chairman of the health committee who regretfully admitted that "whatever their calling they were all in error sometimes; he was himself sometimes as a bricklayer," and eventually it was decided by 27 votes to 16 not to publish the names We are, however, left in some doubt as to the part which the suggestion that publication would lay the council open to legal proceedings played in bringing about this happy ending. Possibly, if Battersea councillors had any practical experience of the difficulty of diagnosing small-pox they would be a little more charitable; but however that may be we protest strongly against the disgraceful attempt to pillory local medical men to which, under the pernicious influence of the anti-vaccination virus, so many members of the council committed themselves.

THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

THE annual report of this society has just been published. We learn from it that the progress of the society during the past year has been on the whole very satisfactory. The number of cases inquired into during this period in England, Wales, and Ireland (a separate report is issued for Scotland) has reached the considerable total of 34,945 This fact alone ought to constitute a sufficient vindication of the society's existence if such were necessary. At the same time it is encouraging to find in the speech of the chairman, Lord Ancaster, at the annual meeting a statement that the number of prosecutions instituted by the society has diminished. On the other hand, we note that the convictions obtained have been more numerous than previously. This apparent paradox is explained by the fact that the method always preferred by the society's agents where it is available—that of warning delinquents—has proved in many cases an effectual preventive against the practice of cruelty. Consequently the term prosecution has become narrowed in its meaning and it now includes a larger proportion of those inveterate forms of tyranny which can only result in a punitive sentence It is gratifying to learn on the same authority that the attitude of the judicial bench is becoming increasingly friendly to the procedure of the society Lord Alverstone has spoken in high praise of its work, which, in the language of another eminent judge, has been carried on with great prudence and forbearance and without needless and officious interference We can cordially indorse these expressions of approval. Financially, the society, though not affluent, is in a solvent condition. After meeting last year's expenses it could show a credit balance of £266. The assurance of its president that all funds intrusted to the managing committee are employed exclusively to the best advantage of suffering children requires no confirmation. Those who are conversant with the history and the administration of the society can have no doubt upon this point.

PLAGUE IN BERLIN.

A YOUNG Austrian medical man named Milan Sachs who was studying bacteriology in Berlin has just died as the result of an unusual accident. While injecting a rat with a culture of the bacillus of plague he wounded his hand and contracted plague by inoculation. A hospital attendant who nursed Dr. Sachs during his illness has since been unwell but is now believed to show no symptoms of plague. All the persons who came into contact with Dr. Sachs in any way after his illness declared itself are rigidly isolated in the Charité Hospital. It will be remembered that more than four years ago a similar accident occurred in Vienna and unfortunately resulted in several deaths. An account of this occurrence will be found in several numbers of THE LANCET, commencing with the issue of Oct. 22nd, 1898, p. 1080.

THE RELATION OF CHOLELITHIASIS TO PANCREATITIS.

THE *New York Medical Journal* of May 16th contains an important paper by Dr. Joseph Wiener, jun., on the relation of cholelithiasis to pancreatitis. Anatomical facts lead to the conclusion that a close relation must exist between affections of the common bile-duct and of the pancreas. A stone which obstructs the common bile-duct near the papilla of Vater must obstruct the duct of Wirsung. If the pancreatic secretion cannot enter the intestine microbes may make their way from the duodenum and multiply and set up pancreatitis. Moreover, the obstructed secretion may be forced backward into the parenchyma of the gland producing injurious effects. Opie has collected 32 cases in which pancreatic lesions and fat necrosis were associated with cholelithiasis. In one case a calculus had found its way into the pancreatic duct and caused suppuration. In 26 out of the 32 cases there was fat necrosis. In 1889 Thayer reported the case of a man, aged 60 years, who in the last 16 months of life had repeated attacks of pain in the left hypochondrium and epigastrium followed by jaundice. He became collapsed and died. At the necropsy the thickened gall-bladder was found to contain over 100 calculi. The common bile-duct was dilated to the size of the little finger and in the duodenum was a stone of the size of a hazel nut. The pancreas was large and reddish-brown and there was necrosis of the surrounding fat. In 1896 Kennan reported the case of a woman, aged 36 years, who was suddenly seized with vomiting and pain in the upper abdomen which were followed by collapse. Death occurred in 48 hours. At the necropsy a stone of the size of a pea was found projecting from the papilla and other stones were found in the gall-bladder and common duct. The pancreas was enlarged, intensely congested, and surrounded by local peritonitis. Dr. Wiener relates the following case. A woman, aged 41 years, the mother of three children, was suddenly seized with violent pain in the upper abdomen on Jan. 28th. On Jan. 30th the pain had increased and become colicky. The whole abdomen was tender and the right rectus muscle was somewhat rigid. Appendicitis was diagnosed. In the evening, when Dr. Wiener first saw the patient, the face was pale and anxious; the pulse was 120, somewhat irregular, soft, and compressible; and the temperature was 102·5°. The epigastrium and right hypochondrium were tender and the right rectus muscle was somewhat rigid at the level of the umbilicus. In the right flank was moveable dulness. A two-inch incision was made along the outer border of the right rectus muscle at the level of the umbilicus. On opening the peritoneum some clear fluid escaped. The omentum was studded with small opaque yellowish-white patches. The gall-bladder was distended and there was a large stone in the cystic duct. It was pushed back into the gall-bladder and cholecystectomy was performed. The head of the pancreas felt hard but it was not enlarged. Recovery followed. A piece of omentum which was removed for examination proved to be the seat of fat necrosis.

TOXIC AMBLYOPIA AND OTHER LESIONS DUE TO THE USE OF WOOD ALCOHOL.

IN the *Philadelphia Medical Journal* of May 9th Dr. J. W. Sherer gives an account of the dangers due to the consumption of methyl or wood alcohol in the case of five persons, four of whom had taken part in the festivities of a national holiday, the celebration of the event being marked by the free consumption of cheap alcohol largely consisting of wood spirits. The host, a man aged 32 years, provided himself on July 4th with a considerable quantity of cheap crude spirits of which he himself and his guests, three in number, partook freely on the following day. Within 24 hours he suffered from nausea and attacks of vomiting, headache and vertigo, sweating and partial paralysis, and stiffness of the legs which lasted for three days. About 24 hours after the debauch his vision began to fail and he could only dimly perceive large objects outside the central part of the field of vision. In the centre of the visual field there was total absence of sight (central scotoma) in both eyes. The pupils reacted to light and accommodation and ophthalmoscopic examination showed that the fundus in both eyes was redder than normal and considerably mottled. The sense of colour perception was entirely lost. The characteristic lesions of the eye produced by the drinking of methyl or wood alcohol and of drugs containing methyl alcohol have been described by Professor G. E. de Schweinitz and an account of the same was published in an annotation in THE LANCET of June 7th, 1902 (p 1615). Dr. Sherer adds that the second man who took part in the drinking debauch was less severely affected. He suffered from nausea, dizziness, vomiting, and headache. His eyesight became dim and this dimness lasted for a few days and then began to improve until in three weeks' time vision was quite normal. The third man drank more deeply than his companions, with the result that he had several attacks of vomiting and became very prostrate; he grew delirious and comatose, in which condition he died within a period of 48 hours. The fourth man became totally blind in two or three days and his sight has never been restored since then. The fifth case referred to by Dr. Sherer was that of a woman who swallowed a "small medicine-glassful" of methylated spirits in order to obtain relief from pain attending menstruation. Her condition became worse and she suffered from dizziness, vomiting, and severe headache soon after taking the spirits. At the end of 24 hours her sight began to fail and on the third day she could only dimly recognise large objects in the margin of the field of vision. Central vision was absolutely lost. The pupils reacted to light and to accommodation. Dr. Sherer states that a search through medical literature revealed 25 cases of toxic amblyopia due to wood alcohol. In all of these cases, as in the five cases reported by himself, the loss of central or macular vision was complete in character and generally permanent in duration. The pathological process is a retrobulbar neuritis of the optic nerve, affecting chiefly the axial bundle of nerve fibres arising from the macula lutea. The perception of red is lost first and then the dimness of sight progresses until central vision is lost. Of the 25 cases recorded in literature 23 resulted from the ingestion, and two from the inhalation of methyl alcohol. The latter cases were as grave as the former and the symptoms of dizziness, nausea, frontal headache, and loss of central vision which followed were similar in both sets of cases. Persons should avoid incurring the danger of inhaling the fumes of methyl alcohol, while the use of this substance in medicinal tinctures should be prohibited, adds Dr. Sherer, as a criminal offence. As regards treatment Dr. Sherer points out that no method has yet been proposed for treatment and that cure is almost impossible, since the destruction of the ganglion cells in the macula lutea of the retina and of the nerve fibres arising therefrom constitutes an organic lesion the results of which are irreparable.

INFANT MORTALITY IN BOMBAY, ITS CAUSES AND PREVENTION.

Mr. Dosabhai Rastamji Bardi, senior tutor of the Grant Medical College, Bombay, has reprinted from vol. vii. of the Bombay Medical and Physical Society's Transactions a valuable paper from his pen drawing further attention to a matter of the highest importance. An infant mortality of 593 per 1000 births and of 867·67 per 1000 of the population amongst children under one year of age recorded during 1899 is certainly very disquieting, especially so when we find that matters have been growing worse year after year. The acting health officer in his report for 1899 says: "The infant mortality can only be called appalling, a little less than one quarter of the total mortality being of children under five years of age and the greatest mortality of any age is that of infants under one year." For the eight years 1892–93 to 1899–1900, 70 per cent. of the total child mortality was amongst infants under one year of age. Thus there is nearly seven times the mortality of infants under one year of age compared to the mortality in England. The state of affairs which is revealed by the figures of infant mortality is alarming and unless serious and earnest efforts are made to improve it Bombay must be prepared to rank very low in the scale of civilisation and to have a permanent stigma on its sanitary condition. In addition to the ordinary conditions which bring about the deaths of children in all communities the special causes in Bombay appear to be the unhealthy surroundings, both natural and artificial, abject poverty rendered more keen and unbearable by famines and epidemics, and the superstitions and prejudices of the ignorant masses. Since 1892 there has been a steady increase in the number of the still-births; these have nearly doubled within a decade. The broad groups of maladies causing deaths among infants show that infant life is not so resistant to diseases as it ought to be and has not that recuperative power which a growing body ought to have. Debility and respiratory and nervous diseases cause the greatest havoc among infants. The number of still-births is a proof that infants are not born in healthy surroundings or such as are likely to favour their growth and vitality, and, further, that they are not sufficiently well nourished in utero. The paper contains several tables, one of which (Table IX.) deals with the "causes of deaths in children under five years of age in different castes and races," and shows that one factor in the causation of increased mortality in infants is a low social scale. The remarks of the health officer in his report of 1899–1900 to the effect that small-pox was confined to children below the age of five years and was worst during the first year of life sufficiently indicate the necessity of making efforts to vaccinate all infants before they are four months old. It is a curious and significant fact that among the poorer as well as the higher classes there has been a general complaint of want of breast milk in nursing mothers; infants are therefore subjected to artificial feeding—a serious menace to the health and growth of the infant population and one which points to a deterioration in the health of mothers, due to bad hygiene, debility from mismanagement during and after parturition, effects of poverty, and other similar causes requiring careful and thorough investigation. Mismanagement during childbirth is an important factor in the high early death-rate and the writer draws a vivid picture of the dirty, overcrowded room in which the Hindu female is confined and of the after-treatment she receives. Mr. Bardi draws attention to the circumstance that many women of the labouring classes are bread-winners and though they may have a proper and good supply of milk they cannot for obvious reasons keep regular hours for feeding their infants; therefore in the course of time the good milk gets deteriorated in quality by being retained in the breasts for long hours. As a remedy he suggests the building of *chawls* for the mill operatives and nurseries in connexion with the mills where women can leave their infants in charge of good nurses and feed them at proper intervals. In discussing the different food substitutes for mother's milk, Mr. Bardi calls attention to the difficulty of obtaining a good supply of cow's milk, to the absence of control over milch cattle and their owners, and to the notorious fact that the people of Bombay are very badly off in the matter of their milk-supply. Mr. Bardi says that the milch cattle stables in many parts of Bombay display a state of affairs not at all creditable; they are ill-kept, ill-ventilated, ill-drained, overcrowded, unpaved or badly paved, and situated in populous localities—"the food given to the animals is generally of the coarsest and very often little more than stable refuse, and they are watered from the nearest dirty tank." The remedial means for the heavy mortality should, the writer suggests, be in the direction of—(1) adoption and enforcement of sanitary laws and measures; (2) education of the masses, with special reference to knowledge of the first principles of hygiene by tracts, lectures, and the like; (3) minimising the ill-effects of the necessary industrial conditions of the poor; and (4) the establishment of large lying-in asylums and the building of sanitary houses for the poor.

RECENT CENSUS PUBLICATIONS.

IN the course of last May two important blue-books were issued from the Census Office. The first consists of a volume of summary tables extending to 300 pages and showing the area and number of houses and of population (with details as to occupation) for England and Wales as a whole—the corresponding facts for the several counties having been published in 53 separate "county parts," at intervals during the previous two years. The second volume contains the census returns for the "Islands of the British Seas," separate details being given for (1) the Isle of Man, (2) Jersey, and (3) Guernsey and the adjacent islands. In a preface we are informed that although the results of the census were tabulated, analysed, and published in England and the schedules and other necessary documents were supplied by our Census Office, nevertheless the enumeration was actually carried out locally by the authorities of the several islands concerned. The ground covered by the present volume is similar in character to that of the corresponding volume issued after the census of 1891; according to the introductory note, however, the tables relating to the occupations of the islanders have, in common with those of the mother country, been considerably elaborated and a table has been added, identical in form with the English table, showing the ages of married and also of unmarried people in each of the islands included in the returns. To the student of statistics the blue-book first referred to may be considered in some respects the most useful publication of the census. The county parts will, of course, be referred to for minute local details concerning those areas, especially when the alphabetical index is available, the publication of which is promised at an early date; but for the ordinary reader the summary tables will furnish all the information required for a general survey of the results of the recent census. In a work of such colossal proportions as the present, involving the preparation and seeing through the press of not less than 53 folio volumes, each containing at least 37 full-page tables, it would be unreasonable to expect complete freedom from mistakes; but we are willing to admit that the table of *errata* which forms the concluding portion of the present volume is not more extensive than might have been anticipated, having regard to the complex nature of the undertaking. Like its predecessors the present volume is signed by Mr. W. C. Dunbar, Registrar-General, by Mr. N. A. Humphreys, and by Dr. J. F. W. Tatham. In a brief introductory note the signatories state that the final report on the census is now in hand and will be published with all despatch compatible with the exercise of that care which the importance of the work demands.

DIPHTHERIA AND PREGNANCY.

The *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of May 17th contains an interesting paper on the above subject by Dr. Chambrelent and Dr. Micheleau in which the following case is described. A woman, aged 44 years, eight months pregnant, was admitted to hospital on March 1st. Eight days previously her throat became sore and hoarseness, aphonia, and difficulty in breathing soon followed. On admission there were all the signs of laryngeal obstruction, stridor, retraction of the supraclavicular and suprasternal fossæ, and turgescent cervical veins. The throat was red but no false membranes were seen. The temperature was 101·4° F. and the pulse was 120. Antitoxin was injected. Two hours after admission the dyspnœa had so increased that tracheotomy was necessary and membrane was expelled through the tracheotomy wound. A second injection of antitoxin was given and the respiration became almost normal. On the following day the temperature had fallen to 97·7° and the pulse to 100. The fœtal heart was heard. On the next morning the dyspnœa recurred. On the left side of the chest no respiratory sounds could be heard and on the right the respiratory murmur was weak. Aspiration through the tracheal wound failed to remove any membrane. The fœtal heart was distinctly heard. After consultation it was decided to induce labour and to make arrangements for Cæsarean section should death supervene. A long œsophageal bougie was introduced into the uterus. The bougie fell out after two and a half hours and no uterine contractions were apparent. Death occurred at 3 A.M. on the following morning. An attempt to introduce the hand into the uterus in order to perform version and to extract the fœtus failed since the os was not dilatable. Cæsarean section was at once performed. The fœtus showed no signs of life and all means of resuscitation failed. The necropsy showed that the larynx was covered with false membrane but that the trachea was free from it. The bronchi as far as the branches of medium calibre were lined with membrane. The lungs were emphysematous and there was emphysema of the mediastinal tissue. In the small bronchi was sero-purulent exudation. The false membranes yielded on cultivation the long bacillus diphtheriæ and diplococci. Very few cases of diphtheria in pregnancy have been recorded. All writers regard the condition as grave. Of 12 published cases in which antitoxin was not used six were fatal but four cases in which it was used were all successful. An interesting point is the great tendency of the diphtheritic process to extend to the larynx, as in children, and contrary to what is usual in adults. Thus in 12 cases published before the introduction of antitoxin tracheotomy had to be performed seven times. It is noteworthy that in the case now recorded there were no signs of uterine contraction although the asphyxia of pulmonary disease is regarded as one of the most important causes of abortion. The diphtheria bacillus was not found in the fœtus but its toxins appeared to have produced profound alterations in the fœtal organs. The myocardium showed signs of degeneration. The spleen was congested and the seat of interstitial hæmorrhages The liver also showed interstitial hæmorrhages, accumulations of leucocytes in the portal spaces, and degeneration of the hepatic cells. The kidneys showed similar but less marked changes. In the lungs there were interstitial hæmorrhages.

THE DISTRIBUTION OF PLAGUE.

As regards the Cape Colony the acting medical officer of health states that for the week ending May 16th the condition of the various places mentioned below with respect to plague was as follows. At the quarantine station, Saldanha Bay, 2 Asiatic males remained under treatment in the hospital, both being convalescent. At Port Elizabeth 2 cases of plague were discovered—namely, 2 native males on May 11th and 13th respectively, 1 being found dead. At the Plague Hospital 1 European female, 2 native males, and 1 native female were discharged recovered during the week, leaving 10 cases under treatment. Plague-infected rats continued to be found in the town during the week. At East London 3 cases of plague were discovered—namely, 1 Indian male on May 10th, 1 coloured male on the 15th, and 1 European female on the 16th. At the Plague Hospital 1 coloured male and 1 native male died during the week, leaving 3 cases under treatment. At King William's Town 1 case of plague was discovered—namely, 1 European female on May 10th. At the Plague Hospital 1 native male died and 1 European female was discharged recovered, leaving 5 cases under treatment. At Graaff-Reinet and Burghersdorp no cases of plague and no plague-infected rats were discovered during the week. At Queenstown plague-infected rats were discovered in the town. In the Cathcart district during the week a plague-infected rat was discovered in the police camp, about one and a half miles from Thomas River Station. As regards Hong-Kong a telegram from the Governor, received at the Colonial Office on June 4th, states that for the week ending May 30th there were 123 cases of plague, 4 in Europeans, with 103 deaths.

EMPYEMA NECESSITATIS WITH THREE PULSATING TUMOURS.

In the *New York Medical Journal* of May 9th Dr. F. P. Henry has re-published a case which he recorded in the Transactions of the Philadelphia County Medical Society for 1881. He has done so wisely, as the case is very uncommon and is practically inaccessible to students of the rare condition of pulsating empyema. A woman, aged 30 years, was admitted to hospital on April 14th, 1880. On the left side of the chest were three strongly pulsating tumours—one in the mammary region of about the size of half a large orange, a smaller conical one in the eighth intercostal space in a line with the anterior axillary border, and the largest one, four inches in diameter, in the postero-inferior region. On palpating the first tumour splashing sounds were produced and a sensation was felt like that of handling a hernia. Evidently the tumour contained both air and fluid. The left chest was dull posteriorly as high as the middle of the scapula. The line of dulness curved downwards and forwards. The whole pulmonary area in front was almost tympanitic and the anterior tumour was decidedly tympanitic. The semilunar tympanitic area of Traube was absolutely dull. The respiration was amphoric except over the posterior tumour. Paracentesis at the site of the conical tumour yielded more than a quart of thick offensive pus. As some air escaped it was thought best to desist. The pulsation in the anterior tumour and the gurgling on palpation ceased and the posterior tumour greatly diminished in tension. The empyema was drained. Of the further history all that is known is that the patient was alive a year afterwards. Only 83 cases of pulsating pleurisy and only one other case with three pulsating tumours appear to have been recorded.

THE ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

WE have the pleasure of announcing that the Enno Sander Prize of the above association has this year been conferred upon a British military surgeon—namely, Major Frederick Smith, D.S.O., R.A.M.C. The subject of Major Smith's essay is "The Differential Diagnosis of Typhoid Fever in its Earliest Stages." The announcement of the fact that the prize went for this year to an officer of the British service was received by his American *confrères* with generous and prolonged applause and much pleasure was generally expressed at the honour which the association was enabled to show to a member of a service towards which all American medical officers feel so kindly. We are sure that this fact will go to cement still further the friendly relations which exist between Great Britain and the United States and to advance the labours of the members of the medical departments of the two great English-speaking nations of the world.

THE annual general meeting of the Poor-law Medical Officers' Association of England and Wales will take place on Tuesday, June 30th, at the Trocadéro, Piccadilly-circus, London, W., at 6.30 P.M. At 7.30 the members and their friends will dine together, Dr. Farquharson, M.P., the President, being in the chair. Any Poor-law medical officer desiring to be present is requested to communicate with the honorary secretary, Dr. M. Greenwood, 9, Copthall-avenue, E.C.

THE annual banquet of the Association of British Postal Medical Officers will take place on Friday, July 17th, at 7 for 7.30 P.M., in the Whitehall Rooms of the Hôtel Métropole, "to meet the Right Honourable Austen Chamberlain, M.P., His Majesty's Postmaster-General."

THE Cavendish Lecture of the West London Medico-Chirurgical Society will be delivered on Friday, June 26th, in the town hall, Hammersmith, at 8.30 P.M., by Professor T. Clifford Allbutt, the subject being Atheroma of the Ascending Aorta.

THE provincial meeting of the Society for the Study of Disease in Children will be held at Brighton on Saturday, June 20th. Several communications on interesting subjects have been promised.

A DINNER of the Durham University Medical Graduates' Association will be held at the Café Royal, Regent-street, London, W., on Thursday, June 25th, at 7.30 P.M.

THE sixty-fourth annual dinner of the Irish Medical Association will be held in the town hall, Enniskillen, on Wednesday, June 17th, at 7.45 P.M.

WEST CORNWALL INFIRMARY, PENZANCE.—At a meeting of the subscribers to this institution held on May 23rd, under the presidency of Prebendary Hedgeland, it was decided to enlarge the building. A quarter of an acre of land to the north of the infirmary will be purchased and the extension will provide for six more beds, the widening of the corridors, and other improvements. The cost of the undertaking is estimated at £4000.

THE ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

THE twenty-ninth festival dinner of the Royal Medical Benevolent College, Epsom, was held on June 10th in the Grand Hall of the Hotel Cecil, Strand, London. The chair was taken by H.R.H. the PRINCE OF WALES.

After the toast of "The King" had been proposed by the PRINCE OF WALES and duly honoured, Sir WILLIAM S. CHURCH, Bart, K.C.B., President of the Royal College of Physicians of London, proposed the toast of "Her Majesty Queen Alexandra, their Royal Highnesses the Prince and Princess of Wales, and the other Members of the Royal Family." He said that the Queen when she first came to this land captivated the people by her beauty, but since then the nation had learned to love her for herself. He thanked the Prince of Wales for filling the office of chairman on that occasion and reminded those present that the King was with the Prince Consort in 1855 when Epsom College was opened and as recently as 1895 the King had visited the College and laid the foundation-stone of the lower school. He concluded by describing how Princess Christian had worked for the improvement of hospital management and nursing.

The PRINCE OF WALES, in acknowledging the toast, said: In the name of the Queen and of the Princess of Wales and the other members of my family and on my own behalf I beg to thank Sir William Church for the very kind and flattering terms which he has used in proposing this toast and I am, indeed, most grateful to you all for the hearty reception which you have given to it. I know from the Queen and the other members of my family that the medical profession may ever rely on hearty sympathy and ready support in their work and in every undertaking which may tend to mitigate the suffering of our fellow creatures. So far as the Royal Medical Benevolent College is concerned I can assure you that the Queen remembers with great pleasure the visit she paid to the College with the King when he laid the foundation-stone of the lower school eight years ago. As Sir William Church has reminded us the Prince Consort opened the College almost 50 years ago and on that occasion he was accompanied by the King. I believe that it was not very many years ago when the King took the chair here at one of your festival dinners and on that occasion he got the largest collection of those days and I hope that to-night we shall beat it. I trust that my presence here this evening will be regarded as a proof that I continue to take the same interest in the College that my family have done since its foundation. As president of five of our large London hospitals I know what splendid service is rendered by the medical profession to those institutions. Also as president of the King's Hospital Fund for London I fully realise the valuable gift of their experience and time in assisting those who control the administration of the Fund. This assistance is most especially valuable in the all-important work of visiting and reporting upon the hospitals that are desirous of receiving help from the Fund. Deeply impressed as I am with what we owe to the doctors and surgeons of this country it gives me the greatest pleasure to take the chair here this evening, and I once more thank you all for the very hearty manner in which you have received this toast and for the kind way in which you have come here this evening to support me by your presence.

The PRINCE OF WALES, again rising, said: I have now the pleasure of proposing the toast of the evening, which is "Success to the Royal Medical Benevolent College." No excuse is necessary for pleading the cause on behalf of which we are assembled here to-night. The charitable institutions of our country are among those national characteristics of which we are justly proud; and I can hardly imagine that there are any more deserving of public support than those whose object is to help members of the medical profession or their families, who, through misfortune or otherwise, are brought to reduced circumstances. I feel that I am uttering a mere commonplace in stating that we all owe a debt of gratitude to the doctor. We cannot get on without him. He is with us on our entry into the world and when we leave it and is our confidential friend from the cradle to the grave. We consult him, confide in him, trust him, though he often has to tell us disagreeable truths. There are few of us who have not reason to be deeply grateful for his knowledge, tender care, and patient watchfulness, by which we have been brought through a severe and dangerous illness. Certainly I myself can speak feelingly as one of that number. But I go further: for over and above our individual thanks you will, I know, agree that our medical profession has earned the heartfelt gratitude of the whole nation; for, thanks to the marvellous progress in medicine and surgery and individual knowledge and skill, the life of our beloved Sovereign was, under the blessing of Providence, preserved to us during the past year. We must also remember, in estimating the splendid work accomplished by our hospitals, that nine-tenths of the medical advice—and this is certainly the best in the country—is given practically gratuitously. But the debt to the doctor is not merely one which is to be considered as discharged as soon as his bill for professional service has been paid. There remains the sense of gratitude which, I am glad to say, often not only finds expression in a sincere and lasting friendship between doctor and patient, but in thank-offerings by which this institution with other medical charities has materially benefited The question may be asked whether the medical profession should not be able to support its own charities without appealing to the public. In answer I would remind you that the popular idea that doctors are rich men is a very erroneous one. True it is that there are a few wealthy members of the profession, but these you may probably count on your fingers. I know, also, that great generosity is shown among these few to their necessitous brothers. Some are able to make a fair income and perhaps to save money, but too many are underpaid and struggle in an overstocked market, and the fact remains that there is an enormous residuum of medical men who live only from hand to mouth. Another common idea seems to be that doctors live for ever. Unfortunately here again is another fallacy. Too many succumb to the hard life of exposure by which their constitutions are undermined or to the dangers of infection. The two following cases are among those recently before the notice of the College. A medical man was summoned to go over the Wiltshire Downs to see a child who had been burned. On the way there he himself was struck by lightning and killed, leaving a widow and large family. A surgeon-major in the Army Medical Staff was compelled to retire from the service on account of complete loss of sight resulting from overwork and hardship on active service. He has a wife and five young children, is not strong himself, possesses but limited means, and partly supports his mother. But it is not only with these conditions of everyday life that the medical practitioner has to contend. We know how in actual warfare he risks and indeed often loses his life while tending those who have fallen in battle and we must not forget that many (I know that some of them are here to-night) gave up the comforts of home life and, regardless of any pecuniary sacrifice, volunteered for service in South Africa. To meet this distress about £14,000 a year is given by three great medical societies in the metropolis—the Medical Benevolent Fund, of which my old friend Sir William H. Broadbent is president, the Society for the Relief of Widows and Orphans of Medical Men, and the Epsom Medical College. The College was founded by Mr. John Propert in 1855 to supply the want which his experience as a family medical practitioner forced upon his notice. The school supports 50 boys on the foundation, the boys being clothed, educated, and maintained. There are also 50 aged or necessitous medical men or their widows who receive £30 a year and to maintain these £8000 a year is necessary. I am very glad to have had the opportunity yesterday of personally visiting the College at Epsom. I was delighted with everything that I saw there; indeed, one could not help feeling that the wishes and aspirations of the founder have been to a great extent fulfilled. I heartily congratulate the head master, Mr. Hart Smith, on the happy and healthy-looking boys under his charge whom I had the pleasure of seeing in the cricket field. But I wish it to be clearly understood that this appeal is not for the school proper, which is conducted as a public school and is self-supporting. It is for necessary funds to support its medical foundation—that is, the education of the 50 foundationers and to maintain the pensions to which I have just referred. And I am glad to be able to state that there are strong reasons for believing that if we receive to-night liberal support it will not be necessary to have recourse to further special appeals. My only regret is that this appeal has not been urged by someone more eloquent than myself. But no one could speak with more profound conviction than I do of the worthiness of the claim which the Royal Medical Benevolent College has upon the sympathy and generosity of us all. I now beg to propose, "Success to the Royal Medical Benevolent College," coupling with it the names of the president, my noble friend Lord Rosebery, and the treasurer, Dr. C. Holman. In its president the institution has to be congratulated. For Lord Rosebery, while ably fulfilling the duties of that office, proves himself to be a true friend and neighbour, showing a keen interest in the general welfare of the College as well as in the boys, their work and their recreation. I feel it presumptuous for me to speak about Dr. Holman. His name is familiar to everyone who knows Epsom College; he is the mainspring of its life. Associated with the charity since its foundation, he has for 16 years worked unceasingly as treasurer and has left a lasting proof of his efforts as an honorary local secretary in the £8000 which he has collected during 38 years in that office

This was responded to by Lord ROSEBERY, the President of the College, who said: My task on this occasion is happily a very small and insignificant one, for it is only to obliterate myself as soon as possible in favour of my working partner, Dr. Holman. Indeed, Sir, if I had had any idea of making an extended speech that would have been dispelled by the one to which we have just listened. The only part of that speech which I venture to disagree with is that in which you said that there can be a better and more effective chairman than yourself. I venture to challenge any orator, however practised he may be, to vie with the pathetic, the eloquent, and what is more the true, terms in which you have spoken of the medical profession. We have so many of them here to-night that I hardly dare to think and I scarcely venture to conjecture what may be the effect on their patients in London. The titled cynics of the profession in whose immediate neighbourhood I am sitting have given vent to their conjectures on the subject, but I will not venture to imitate them I will only hope that all may be for the best—and I think that I will pause there for fear I should give utterance to some imprudent sentiment. I confess that I do not like to call myself an impostor, yet this is the thought that is present in my mind now, but I am, strange as it may seem, an ornamental figure on this occasion. I am indeed President of Epsom College, but I am responsible neither for its teaching nor for its discipline as other presidents of other colleges are. If I were I might have to give a less favourable report on both than I conscientiously can on the present occasion. If I had my way I should like to exchange my office with that of the Bishop of Winchester and become a visitor of the College, because in that capacity I am genuine and frequent and should not blush to reply on behalf of the College as I do now. I am indeed at Epsom happily a neighbour and I have the great pleasure and privilege of being frequently a visitor of Epsom College owing to local circumstances, much more frequently I suspect than any occupant of the See of Winchester. Well, I can offer no report on the studies of the place and Mr. Hart Smith gives me no access to them and never asks my opinion or judgment on them, but as regards the more athletic features of the College I can say from some experience—as you, Sir, have been able to say from your experience of yesterday—that a finer and healthier and manlier lot of students exist in no other educational establishment; they live in the finest air in the world, they are kept carefully exempt from the temptations which are associated with the name of Epsom and they are, I believe, prepared to go anywhere or to do anything. There is only one drawback connected with the College and I hope that it may be the result of this meeting to-night to remove that drawback: it is the word "benevolent" in the title which I think is a considerable drawback to its success. I have lived for some years as President of the Royal Medical Benevolent College of Epsom and if I can die president of the Royal Medical College of Epsom I shall be content. I hope, Sir, it may be your destiny to-night to accomplish that great work. There have been many chairmen before you and there have been many successful banquets before this one, but I hope that when this is over we shall be able to say in the words of the psalm of triumph that whereas the chairmen before you have collected their thousands you have collected your tens of thousands.

Dr. HOLMAN, the treasurer, said that on behalf of his colleagues on the council of Epsom College he thanked His Royal Highness for his presence and for the terms in which he had commended the cause of the pensioners and foundation scholars of Epsom College. The present gathering was the largest ever seen in the metropolis in the cause of a medical charity and he hoped that His Royal Highness would accept it as the grateful recognition of his kindness in presiding. Personally he thanked His Royal Highness warmly for his speech, it contained much of what had been his opinion for so many years of the relation of the public with the medical profession which coming from His Royal Highness would, he hoped, leave a stronger and more lasting impression than coming from any medical man. He gratefully acknowledged the practical sympathy received from some members of the public who had recognised the services the medical profession rendered to society and to the public health. But since he had been engaged in preparing for this dinner he had come to handgrip with an attitude of mind which had apparently militated against a more generous recognition of the claims which the medical profession might justly make upon every section of society. That His Royal Highness should have recognised and placed them before that meeting was a matter of intense satisfaction. His Royal Highness had touched upon the question of medical men who earned large incomes. These men began to earn late, their work was personal and their harvest-time was short and he, Dr. Holman, bore testimony that they gave generously for the relief of the necessitous of their profession. There was a considerable class who might give each year sums which they would not miss but who seemed to shrink from giving because the amount would look small. THE LANCET had stated how much good would accrue if 10*s.* a year were contributed by each medical man, but if every practitioner in the United Kingdom would give half-a-crown yearly there would be no further anxieties for Epsom College. He thanked His Royal Highness for recognising that there must be suffering, want, and distress amongst them; accident and disease must attend upon the practice of medicine and when the bread-winner was gone how terrible were the straits to which the widow and children of such a man might be reduced. He ventured to indorse His Royal Highness's position that the medical profession had claims upon the public which were not sufficiently recognised. Hospitals were built and maintained by the public. Was sufficient thought given to those by whose labours the relief of sickness and suffering was secured within their walls? The medical profession supplied the staff, but to be a physician or surgeon to a hospital did not insure success in private practice. He had the pleasure to announce that since the preparations for the dinner had been in hand the two daughters of the late Mr. Leach of Shaw, near Oldham, had given the council £1000 to found a Leach Memorial Scholarship of £50 a year tenable for four years to be awarded without competition to a boy requiring assistance to enter at either Oxford or Cambridge, preference being always given to the orphan sons of medical men. The Anstie Memorial Scholarship held for the like term would now enable a scholarship to be awarded every two years.

The grand total of the subscription list was then stated to amount to £6526, this announcement being received with cheers.

The company separated after the Prince of Wales had departed, his exit being accompanied by the singing of "For He's a Jolly Good Fellow."

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on June 8th, Sir James Crichton Browne, treasurer and vice-president, being in the chair. Sir Walter J. Sendall, G.C.M.G., was elected a member.

CORK MEDICAL AND SURGICAL SOCIETY.—The annual general meeting of the members of this society was held on May 27th, Dr. P. T. O'Sullivan, the President, being in the chair. [illegible] £68 to the cred[illegible] elected for ne[illegible] President: Dr. N. Henry Hobart. Honorary secretary: Dr. D. J. O'Connor. Honorary treasurer: Dr. P. J. O'Brien. Council: Dr. P. T. O'Sullivan (retiring President), Dr. C. Y. Pearson, Dr. W. E Ashley Cummins, Dr. T. G. Atkins, Dr. H. R. Townsend, Mr. E. Murphy, Mr. P. G. Lee, and Dr. Lucy E. Smith. Dr. N. J. Hobart, who has retired from active practice after a professional career of 57 years, was unanimously elected an honorary life member of the society.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE KING AND QUEEN AT ST. PAUL'S CATHEDRAL.

THE very real interest taken by the King in the welfare of the hospitals and dispensaries of the metropolis was further emphasised by the visit of His Majesty to St. Paul's Cathedral on Sunday afternoon last, when a collection was made on behalf of the Metropolitan Hospital Sunday Fund, and when there were also present the Queen, the Prince and Princess of Wales, the Duke and Duchess of Connaught, the Princess Henry of Battenberg, the Princess Christian, the Duke of Cambridge, and other members of the Royal Family. The Cathedral was well filled long before the commencement of Evensong at 3.15. The congregation was largely composed of the middle and working classes, who joined their intercessions with those of their Sovereign and the Royal Family on behalf of the good work done in the [illegible] the [illegible] of Men of the words "especially those in the London hospitals for whom our prayers are desired," and a commendably brief and appropriate sermon by the Bishop of Stepney from the text, St. Luke xxii., 24, 25, and 26: "And there was also a strife among them, which of them should be accounted the greatest. And He said unto them, The kings of the Gentiles exercise lordship over *them*; and they that exercise authority upon them are called benefactors. But ye shall not be so: [illegible] let him be as the younger; [illegible] th serve." In the course [illegible] that there was nothing great in position unless it was used as a power for wider service; nothing great in wealth unless it was used as an opportunity for helping others. If this were forgotten, even though they seemed to succeed, they were making a great failure—they were abdicating the true royalty of human life, its capacity of compassion. And on that day an appeal came for their compassion with peculiar force and urgency. Hospital Sunday brought before their imagination the vast tide of pain and suffering which their hospitals were trying with such noble patience and devotion to stem. If one poor sufferer were brought before them there was not one of them who would not do what he could to help. But it was not one poor sufferer, but the 105,000 in-patients and the 1,670,000 out-patients in the London hospitals who were, as it were, laid at their door. And to lend, if it might be, force to their plea, their Gracious King and Queen with the members of the Royal house had associated themselves with it by their presence, illustrating the true royalty of compassion, proving once again that it needed no proof that here in England "the throne is upholden by mercy." Such an appeal on behalf of the poor and sick must act as a test of the real worth of their character. If it left them unmoved, asking only what was the least that could be expected of them, then their poverty of life was discovered; it was plain that the disease of selfishness was upon them. On the other hand, there was still, in spite of all their sins and shortcomings, some element of greatness left in them, something God-given and God-like, if their hearts moved forth to meet the appeal in the ardour of compassion. What might not be done to establish on a sure foundation those homes of mercy, to banish the shadow of anxiety which haunted the efforts of the devoted men who were responsible for them, if every person in that great congregation, rich and poor alike, asked, in eagerness for the answer, "What can I do, by thought and influence and self-denial, for the hospitals of London?" Lastly, if it were true of each individual man that his real worth was tested by his capacity of compassion, it was equally true of the community to which he belonged. The greatness of a nation consisted not so much in the number of its people or the extent of its territory or the mass of its wealth as in the strength and width and justice of its compassion. They were proud of the greatness of the city of London, but its size was a thing to appal, not to uplift, unless it spoke of one body in which the strong and the weak, the rich and the poor, were bound together by the ties of mutual help and common service. Its wealth was a mere golden idol upon feet of merest clay unless it was used as a trust for the public good, an opportunity for the exercise of compassion. Their hospitals stood in their midst as a constant reminder, "lest we forget, lest we forget" the true greatness of the city: St. Bartholomew's, witnessing in the very centre of the city to the kindness of an olden time; the London Hospital, rising above the crowded streets of the East-end; St. Thomas's, confronting the centre of the Empire's labours; St. George's, standing in mute appeal as the stream of wealth and luxury flowed around it. The hospitals were voices calling to London, "Remember, O remember, the Lord thy God; remember the trust with which He has charged thee; remember the poor, the suffering, and the stranger at thy gates." There were many signs that the city was not deaf to the call—the King's Fund, the generosity of men such as he who had again come forward to stimulate his fellow-citizens, the steady growth of the Hospital Sunday Fund. All these were tokens of a quickening of the public conscience. But could it be said that the wealth of London had yet risen to the height of its opportunity? If it had, would it be possible that the annual deficit of the hospitals should be £250,000? Already there were ominous declarations that the strain of raising funds had reached the limit of endurance and that ere long the hospitals of London must turn to the compulsory help of the rates. Doubtless a city could exercise much of its common service through its rates. Doubtless the skill of the physicians and the devotion of the nurses would not fail if the hospitals became public institutions. But good which was done under the compulsion of "must" could never have the moral worth of good which was done under the obligation of "ought." The performance of a public duty was a thing far finer, far more uplifting, when it was freely offered. To remove from the walls of our hospitals the old familiar words, "Supported by voluntary contributions," would be an act of moral retreat on the part of a great and wealthy city. The appeal of the hospitals for more assured and more continuous support was therefore an appeal to the honour of the city. God grant that that notable day might mark the beginning of a more resolute and sustained effort by the great city of London to prove that its power, like the power of God, from Whom it came and to Whom it was responsible, was declared most chiefly in showing mercy and pity.

The collection was taken by a staff of some 60 persons and realised £4300.

Special Meeting at the Mansion House.

A meeting of the members and supporters of the Metropolitan Hospital Sunday Fund was held at the Mansion House on June 8th, under the presidency of the LORD MAYOR of LONDON, to further the interest in our hospitals and medical charities. Among those present on the platform were the Lady Mayoress, the Archbishop of Canterbury, Sir R. Douglas Powell, Bart., K.C.V.O., Sir Frederick Treves, Bart., K.C.V.O., C.B., Sir William S. Church, Bart., K.C.B., Sir Sydney Waterlow, Bart., Sir William H. Broadbent, Bart., K.C.V.O., Mr. Wakley, Dr. J. G. Glover, the Archdeacon of London, Monsignor Stanley, Mr. Richard B. Martin, M.P., Rev. Prebendary Ingram, Mr. R. de Q. Quincey, Mr. Thomas Bryant, Alderman and Sheriff Sir G. Truscott, Rev. Prebendary Ridgeway, Captain A. Palliser, Rev. A. Harlow, Sheriff Sir Thomas Brooke Hitching, Rev. G. H. Pearce, Rev. Canon McCormick, Rev. C. H. Grundy, and Mr. F. H. Norman.

Letters of regret for absence were received from the Bishop of London, the Bishop of Rochester, the Bishop of St. Albans, the Bishop of Islington, the Bishop of Kensington, the Bishop of Barking, the Bishop of Southwark, the Dean of Windsor, Monsignor Poyer, the Dean of Westminster, the Rev. Canon Fleming, Dr. Hermann Adler (Chief Rabbi), the Duke of Norfolk, Lord Stamford, Lord Sandhurst, Sir Edwin Durning Lawrence, Sir Savile Crossley, Bart., M.P., Sir Horatio Davies, M.P., Mr. C. E. Tritton, M.P., and others.

The LORD MAYOR in opening the proceedings said that they had met with the object of advocating the claims of the Hospital Sunday Fund and he was pleased to tell his hearers that an excellent beginning had been made by the collection at St. Paul's Cathedral on June 7th which amounted to £4300. How greatly this result was owing to the action of the King and Queen only those closely associated with the Fund could know, and he sincerely hoped and believed that the noble example set by their Majesties would permeate all congregations on June 14th so that their Majesties might have the gratification of knowing that their work had not been in vain and that the collection this year would be a record one.

The Archbishop of CANTERBURY, in moving

> That in view of the great interest taken by their Majesties in promoting the welfare of the metropolitan hospitals this meeting pledges itself to use every effort to make the Hospital Sunday collection a "record" one this year,

said it was necessary to emphasise the fact that the corporate life of which they were ordinarily proud was not an empty dream and that those who deliberately set on one side the claims of the London hospitals were placing themselves outside the pale of citizenship altogether. So definite was the call upon them all, and so real and certain were the needs, that he failed to understand the position of those who, while claiming the position and responsibilities of their common life, did not respond to that call. He knew of no other way in which the responsibility of the strong for the due care of the weak could be so obviously shown and exercised as by supporting the Fund which brought them together that day. Chivalry was the first characteristic of some centuries of their nation's life. A good many years ago chivalry was defined as "the reverence of strength for weakness." They were showing that reverence in pleading for the London hospitals. Who would not be chivalrous? Nearly 400 years ago, in his "Utopia," Sir Thomas More set forth his idea of what was obviously the right and proper way in which a nation with great cities should carry on its work and a good many of those present would no doubt recollect the emphasis which he laid on the part that hospitals must take in the life of his ideal community. In the second book of the "Utopia" were to be found the following words:—

> For in the circuite of the citie, a litle without the walles, they have iiii. hospitalles, so bigge, so wyde, so ample, and so large, that they may seme iiii. litle townes, which were devised of that bignes partely to thintent the sycke, be they never so many in numbre, should not lye to thronge or strayte, and therefore uneasely, and incommodiously and partely that they which were taken and holden with contagious diseases, suche as be wonte by infection to crepe from one to another, myght be layde apart farre from the company of the residue These hospitalles be so wel appointed, and with al thinges necessary to health so furnished, and more over so diligent attendaunce through the continual presence of cunning phisitians is geven, that though no man be sent thether against his will, yet notwithstandinge there is no sicke persone in al the citie that had not rather lye there then at home in his owne house.

From the statistics which they held in their hands his hearers would see how far short London fell four centuries later of the ideals set forward even in Tudor times as regarded either the amplitude of our supply or the necessary funds for its maintenance. But in one other respect we had realised to the full the ideal of the great thinker of the sixteenth century, for we should find it hard to mend the condition of things as regarded what he called "diligent attendance" and "continual presence of cunning phisitians" who were there, and in these later days we had devised something of which Sir Thomas More never dreamed in that great complement to the physicians' work—the presence of a devoted band of nurses. A perusal of the rules relating to nursing 100 years ago would show how much we owed in the present day to the skill of thousands of competent and devoted women who had learned their art in the hospitals. How was it, the Archbishop asked, that the necessity arose year by year to go through the annual process of absolutely entreating the public to do so obvious a duty as the supply of the necessary funds for the maintenance of our hospitals? It was not because people who really knew did not care. It was because those who ought to care did not know and it appeared practically impossible to bring the facts home to them. A few years ago when we were at war, as soon as the needs of the sick and wounded were made clear to England, there was no lack of money to supply those needs. But in the ordinary round of our common prosaic life the needs of our hospitals at home slip out of sight. If we realised how London was crying out at the present time for help for the sick and suffering in our hospitals the miserable annual dole of £50,000 or £60,000 would be multiplied by ten within a week. It would, however, be wrong not to recognise the amount of good that was being done by no small number of rich people quite outside the range of the Hospital Sunday Fund. For the work of these people they the public with tho duty which the corporate life imposed upon them.

the motion, referred to his sympathy and su nday Fund since its foundation, a fact which showed the worthiness of the charity. The committee of the Fund consisted of prominent and well-known men of all denominations who devoted their skill and time to the work of the distribution of the Fund. The laws of the constitution of the Fund enacted that the participating hospitals should have their accounts properly kept and there was a clause in one of the laws which insisted upon the necessity of hospital managers seeing that their charity was not abused. These facts showed how admirably the Fund was administered. As to the educational value of hospitals he felt sure that any patient who entered the wards of our healing institutions could not fail to be filled with the spirit of order and cleanliness. In the wards of the hospitals he would also learn self-denial and self-restraint, virtues which, perhaps, he had never thought of before. The education gained in the wards of the hospital would also, in all probability, be reflected in the patient's family life. In addition to the satisfaction of helping the suffering poor, those who subscribed to our healing institutions should remember that the large and well-equipped hospitals were the fertile centres of advancing medical science. Cases that were treated in the hospitals frequently formed the subject of discussion and interest and valuable information was thus spread among medical men throughout the country. Thus those who were able to subscribe to our hospitals would reap a reward in their hour of need. With the advance of medicine and surgery hospital expenses necessarily increased. At one of the hospitals to which he (Sir Douglas Powell) had the honour of being attached £1200 had recently been spent but this outlay he advancement ient which they brought about. With this increase in the cost of hospitals and appliances better and quicker results were obtained for the patients. He could recall the time when many diseases, medical and surgical, but particularly the latter, used to occupy the beds in the hospital for six, eight, and 12 weeks; now the same cases were discharged in one-half, one-third, and even one-quarter of that time. Therefore, although the expenses might be increasing, the cost per patient, owing to the larger number passed through the same number of beds, was by no means proportionately the same. A short stay in hospital meant a lessened degree of suffering, a quicker return to home life meant a speedier return of wage-earning power, a vast gift to the community. With regard to the use of stimulants, the expenses of hospitals had been greatly diminished. The amount of stimulants given 30 years ago was greatly in excess of that which more recent experience had led them to recognise as useful and to-day alcoholic stimulants were definitely prescribed by physicians and their effects were jealously watched throughout the time the patient remained under treatment. Hundreds of pounds yearly were saved to the hospitals by this watchfulness on the part of those in authority. It might be said that if these institutions were of such public value why not make them rate-supported? Why, it might be asked, should busy, hard-working, and generous people have all this anxiety and trouble to raise funds to keep them going? Reasons might be urged in favour of such a change, but if hospitals were placed on a business footing in this way the qualities of love and mercy now associated with them would vanish and that would be a great loss. The Bishop of Stepney in his sermon at St. Paul's Cathedral on June 7th had said that good done under the compulsion of "must" had not the moral worth of that done under the compulsion of "ought" That represented very much what he (Sir Douglas Powell) wished to say. Let them still endeavour to go on rendering those deeds of mercy to the sick poor and he trusted that the splendid advocacy which many of them heard in St. Paul's Cathedral on June 7th would be repeated throughout London and the country next Sunday and that the response would be such that there would be no necessity for placing hospitals upon the rates.

Sir FREDERICK TREVES, who supported the motion, said that it was almost impossible to realise to what an enormous extent poor man could find shelter when ill or injured. It had now become an absolutely necessary institution in which to carry out methods used in treatment which a quarter of a century ago were entirely unknown. These included hypodermic injection, Roentgen rays, the serum treatment, the treatment by baths, the treatment by the Finsen light, and, above all, the treatment by operation. The extent of the increase in surgical treatment had been almost incredible. 20 years ago the greatest hospital in the metropolis—the London Hospital—possessed only one operating theatre which was occupied only one day in the week. It now possessed five, which were occupied every day. Hospitals at the present time appealed to an enormously increased section of the public. So elaborate were some of the methods of treatment that they could not be carried out at any other place except at a hospital. A broken limb was set under the x-ray light—and that could not be applied in the cottage of the artisan. 20 years ago the hospital was not a popular place. People had a dread of it and they had some reason for their dread, but now the pressure for admission into all the great London hospitals was so enormous that it was scarcely possible reasonably to cope with it. Treatment was extended in hospital to an increased section of the population which included people who might be said to represent almost the backbone of the country. The question might be asked, "What do the charitable public get in return for all their ma faction of having taken par They obtained so much that over. In this country all medical education lay in voluntary hospitals and the efficiency of the medical men who were in practice and who would be in practice in the future depended on the efficiency of our great hospitals. As soon as the hospitals languished from want of funds the effect would be immediate upon our children and grandchildren.

that in a little time a cure would be discovered for cancer. Could he mention any sum, however large, that would represent the value of the gift to the world of that piece of knowledge? It would be discovered, he had no doubt, by some private person in a voluntary hospital as a result of researches carried out there at his own expense and it would be presented to the world absolutely free. They might say that that had not come yet, but a thing as big as that had already come to pass Could any sum of money express what had been the worth to the world of the gift of antisepticism? It was not a mere question of saving pain but of saving life to a degree of which the significance had hardly yet been grasped. That was a free gift to the world by a man who discovered it as the result of researches conducted at his own expense in a voluntary hospital; and he was sure that Lord Lister would say that without the voluntary hospitals of this country—without that liberal attitude which the governing bodies had shown towards scientific work—antisepticism, with its magnificent results, might have been still unknown to the world. Therefore, he thought that, from the lowest point of view, those who had been most generous in supporting our voluntary hospitals could claim that they had had some return for their much-appreciated kindness. There was no more important monument to the British race than the hospitals supported by voluntary contributions and it would be a great loss with no corresponding advantages if the hospitals should become State-supported.

The motion was then agreed to.

Sir WILLIAM S. CHURCH moved a vote of thanks to the Lord Mayor which was seconded, in the absence through illness of Cardinal Vaughan, by Monsignor STANLEY and agreed to unanimously.

In his reply the LORD MAYOR said that the cause which they had met to promote was one in which all creeds participated and he expressed his regret that the Chief Rabbi was unable to be present in consequence of an accident which had befallen him. He (the Lord Mayor) particularly wished to point out that the Metropolitan Hospital Sunday Fund was as much the Fund of the poor man as of the rich man and contributions from a shilling and upwards would be thankfully received.

THE MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.

(*Concluded from p. 1613.*)

Surgical and sanitary appliances formed an important feature of the exhibition this year; under the former we may include electrical apparatus such as is now employed in a number of therapeutic applications and apparatus for the production of a rapid vibratory movement; under the latter may be mentioned examples of special sanitary ware for hospital use, filters, and disinfectants and soaps.

Messrs. Doulton and Co. (Lambeth, S.E.) devoted a good deal of space in the entrance hall to the exhibition of sanitary fittings specially designed for hospital use. Amongst the exhibits were the following: A hospital closet fixed so as to be clear of the floor on iron brackets imbedded in the pottery and provided with a vitreous enamelled pipe to connect the cistern to the closet; a white glazed fireclay sink to be used in the cleansing of either bed-pan or urine bottle and provided with a special combination of hot- and cold-water valves, so that the utensils may be washed out with water at any desired temperature; an elbow-action operating lavatory waste and supply, both being worked by the elbow, while the temperature of the water can be readily adjusted by the same means; and lastly, a white vitreous enamelled cast-iron mortuary table. Messrs. Hendry and Pattisson, Limited, (11, Hill's-place, Oxford-street, London, W.), exhibited a model of a hospital ward stove which supplies a constant stream of pure warm air to the ward besides affording the radiant heat of an open fire in the ordinary manner. It is claimed that the warmed air is not burnt or "devitalised." The stove certainly has a cheerful appearance and from its construction should be economical in use. The treatment of disease by radiant heat and light by the Dowsing method was demonstrated by the Dowsing Radiant Heat Co., Limited (24, Budge-row, Cannon-street, London, E.C.). Close by was a stall devoted to the exhibition of an automatic aerator by the British Automatic Aerators, Limited (Alderman's House, Alderman's Walk, Bishopsgate, London, E.C.). The arrangement enables the aeration of the ordinary water-supply to be made directly without agitation or pumping. The apparatus would seem to be admirably suited for hospital use and it is said that by means of this machine the cost of producing 2000 glasses of aerated water is 6*s.* 6*d.*, or at the rate of 24 glasses for one penny. The Berkefeld Filter Co., Limited (121, Oxford-street, London, W.), showed many forms of their well-known filter which provides a filtrate free from germs so long as proper attention is paid to its regular cleaning and sterilising. We noticed also a rapid tap filter which was shown by the Tap Filter Co. (134, Charing Cross-road, London, W.C.). The use of this filter certainly produces a clean bright water but no evidence is offered so far as we could ascertain as to its removing pathogenic organisms. Messrs. J. Defries and Sons (146 and 147, Houndsditch, London, E.) exhibited a number of Pasteur filters and some illustrations of the Equifex disinfector. Safest of all methods as regards sterilising water is distillation and for domestic purposes the Gem Pure Water Still of the Gem Supply Co., Limited (121, Newgate-street, London, E.C.), is convenient and useful. The hygienic steel bin of the Young's Patent Hygienic Bin Co. (72, Mark-lane, London, E.C.) should be mentioned as offering a clean receptacle for flour, &c., in which there are no internal corners or crevices. Particles cannot thus lodge to become stale and to infect, it may be, fresh additions to the bin. The London Necropolis Co. (121, Westminster Bridge-road, London, S.W.) devoted the space at their disposal to some illustrations and descriptive matter of the process of "natural interment" which they advocate. The coffin aids rather than hinders the natural dissolution of the body. There were not many examples of disinfectants shown. Messrs. Newton, Chambers and Co. (Thorncliff, near Sheffield) exhibited their izal preparations, while the stall of the Jeyes' Sanitary Compounds Co., Limited (64, Cannon-street, London, E.C.), was devoted chiefly to the exhibition of Jeyes' fluid disinfectants, sanitary powders, and creolin preparations. The comparatively new soap preparation known as "petol" is worth attention (Petol Limited, 86, Cannon-street, London, E.C.). The basis of this soap is said to be of a purely vegetable origin, the name suggesting peat as a source. The soap has peculiarly bland properties and is specially well adapted for delicate skins; it is disinfectant and antiseptic and several forms of it for toilet and medical use are prepared. An excellent soap also is Oowana soap, which has received attention in our Laboratory Records (Oowana, Limited, 205, Victoria-street, London, S.W.). Messrs. Wright, Layman, and Umney, Limited (Southwark, London, S.E.), exhibited specimens of Wright's coal tar soap, an excellent sanitary adjunct, as well as some special pharmaceutical preparations. Mr. James J. Hicks (10, Hatton-garden, London, E.C) exhibited a great variety of clinical thermometers for the excellence of which his name is well known. The exhibit comprised also a sphygmometer (including a pocket form), opaque glass measures, and urinometers. Messrs. Leslies, Limited (Hopetoun House, Lloyd's-avenue, Fenchurch-street, London, E.C.), exhibited their well-known tape plasters besides antiseptic dressings, gauzes, strapping, bandages, and belts. Amongst the apparatus exhibited by the General Electric Co., Limited (71, Queen Victoria-street, London, E.C.), were complete sets for faradisation, for galvanism, for electrolysis and epilation, for galvano-cauterisation, for high-frequency treatment, and for the production of x rays. Surgical cutlery and instruments were well represented in the excellent assortment shown by Mr. W. K. Stacy (19, Newgate-street, London, E.C.). Messrs. H. W. Cox, Limited (9, Cursitor-street, Chancery-lane, London, E C.), exhibited x-ray and high-frequency apparatus We have more than once had occasion to mention the excellent results given in x-ray work by the apparatus of this firm. The Medical Supply Association (228, Gray's-inn-road, London, W.C.) showed a number of electro-medical apparatus and surgical instruments. The exhibit included the Gaiffe-Gallot electrolytic interrupter for working coils directly from a main alternating current. It is said that this interrupter gives a steady current and that no valves are required. The Improved Vibrator Co. (167, New Bond-street, London, W.) showed their apparatus for vibration treatment. The whole of the mechanism is inclosed in a flat circular case, and it can be regulated from the most gentle vibratory motion to any frequency desired. Messrs. Thomas Holland and Son (40, South Audley-street, Grosvenor-square, London, W.) exhibited their well-known natural-shaped boots and also their instep arch sock and bunion splint. Messrs. C. Bellack and Co. (12, Marble Arch, London, W.) exhibited a series of vibration instruments of which they are the makers; they are in particular the agents for the Muschik Vibrator. A very wide assortment of hospital appliances was exhibited by Messrs. Garrould (150 to 160, Edgware-road, Hyde Park, London, W.). The exhibit included antiseptic dressings, medical batteries, dissecting instruments, hypodermic syringes, invalid appliances, and many other forms of apparatus which go to make up the *armamentarium* of the surgeon and the nurse. The Marconi Wireless Telegraphy Co. (18, Finch-lane, London, E C.) exhibited apparatus for x-ray work. This company gives special attention to the insulation upon which the efficiency of the coil so much depends. A great number of surgical instruments was exhibited by the Holborn Surgical Instrument Co. (26, Thavies-inn, Holborn-circus, London, E.C.). The appliances for the lame of the O'Connor Extension Co. (2, Bloomsbury-street, London, W.C.) are well known, including their new support for flat-foot and other appliances for weak or deformed feet. Amongst examples of sanitary clothing shown were the aertex cellular clothing (underwear) of the Cellular Clothing Co., Limited (72 and 73, Fore-street, London, E.C), and the Kneipp mesh of the York St. Flax Spinning Co, Limited (2, Milk-street, London, E.C.). Examples of sanitary wood wool preparations, such as tissue, sheets, towelettes, and vaccination pads, were shown by the Sanitary Wood Wool Co. (26, Thavies-inn, Holborn-circus, London, E.C.). Natural mineral waters were represented in the purgative saline water of Friedrichshall (C. Opper and Co. 10 and 12, Milton-street, London, E.C.), and in the sparkling table water from the Rosbach springs (the Rosbach Co., 81, Commercial-road, Lambeth, London, S.E.). Finally, a few of the stalls were devoted to the exhibition of medical literature, the exhibits attracting general attention in this connexion being that of Messrs. D. Appleton and Co. (25, Bedford-street, Covent-garden, London, W.C.), the Scientific

Press, Limited (28 and 29, Southampton-street, Strand, London, W.C.), and Messrs. Rebman, Limited (129, Shaftesbury-avenue, Cambridge-circus, London, W.C.).

PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS.

HEREFORDSHIRE.

THE latest branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis has been established in Herefordshire. The meeting at which the branch was inaugurated was held at Hereford on May 20th and was presided over by the Lord Lieutenant of the county, the audience, which numbered about 130 persons, having been brought together at the instance of the Herefordshire Medical Association. The first president of the branch is the Lord Lieutenant, and the Earl of Chesterfield, the Bishop of Hereford, the Dean of Hereford, the mayors of Hereford and Leominster, the Members of Parliament for the county, and the chairman of the county council have been invited to become vice-presidents. The meeting on May 20th was addressed by Dr. C. Theodore Williams who attended to represent the National Association. Dr. Williams spoke of the comparatively favourable position held by Herefordshire with regard to the death-rate from consumption and he attributed the diminution in the mortality from the disease over the whole of the United Kingdom as mainly due to the administration of the Factory Acts, to subsoil drainage, and to the improved condition of the working classes who now have better food and live in better houses than formerly. Although Dr. Williams admitted that the open-air treatment could be successfully carried out in private he advocated the erection of sanatoriums, because in them people were taught how to live and the influence which the patients exerted upon leaving such institutions did incalculable good among their acquaintances.

WINSLEY SANATORIUM.

On June 4th Lady Dickson-Poynder laid the foundation-stone of the Winsley Sanatorium for consumptive patients from the counties of Gloucester, Somerset, and Wilts. There was a large gathering which included the Bishop of Bristol, Sir John Dickson-Poynder, M.P., Lord Edmond Fitzmaurice, M.P., and Dr. L. A. Weatherly. An administrative block for 60 patients and bedrooms for 20 patients will be built at a cost of £6877 and as funds come in additional accommodation will be provided for patients until the full complement of 60 beds is made up. The funds in hand, after the purchase of the site and other expenses, are £6840 and the building and furnishing will involve an outlay of £8327. To complete the whole scheme about £9000 are required. The endowment of 15 beds in the institution has already been promised.

BELFAST.

The annual meeting of the Ulster Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was held on June 5th in the Medical Institute, College-square North, Belfast, Sir William Whitla being in the chair. The annual report, which was read by Mr. Robert Brown, the honorary secretary, stated that the death-rate from tuberculosis was decreasing in England and Wales but was increasing in Ireland, having risen from an average of 19 per 10,000 during the period 1870–75 to 23 per 10,000 in 1900. Dr. A. K. Chalmers, medical officer of health of Glasgow, delivered an address the title of which was "How to Reduce the Death-rate from Consumption."

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

THERE are only four candidates for the three vacancies on the Council. Mr. H. T. Butlin seeks re-election and Mr. Clinton T. Dent of St. George's Hospital, Mr. Frederic S. Eve of the London Hospital, and Mr. G. H. Makins of St. Thomas's Hospital are also applying. On only a few previous occasions have there been so few candidates.

Looking Back.

FROM

THE LANCET, *SATURDAY*, JUNE 11, 1825.

HOWEVER it may arise, whether because man is an imitative animal, or because his attention is roused to activity by the necessities which surround him, an ardent disposition to act *gregariously* may be plainly perceived; or, in other words, whatever may be commenced by one man is immediately prosecuted by a host of others. But this state of things does not commonly obtain long, some improvement is made, and other more inviting, or more profitable projects succeed, which forthwith, true as shadow to the substance, become the standing order of the day, till the bubble bursts, or till they are deposed to make room for some novel or more specious objects of pursuit, by which means the energies of the flock are directed into other and sometimes, though but rarely, more useful channels Whence arises the present apathy for mathematical investigations? Is it not because the sublime discoveries of NEWTON kindled a spirit of enthusiasm so ardent, that improvements were multiplied and perfection approached so nearly, that in our day the laurels to be gathered are comparatively few and extremely difficult to be obtained? Botany, too, has had its day, and Chemistry has lost much of the attraction which, in our juvenile years, it was wont to possess. CAVENDISH and BLACK, PRIESTLEY and LAVOISIER, are now almost forgotten, and even the name of DAVY is heard but seldom. At one period the study of this science was almost universal; and oxygen and hydrogen, and chlorine and nitrogen, "familiar in men's mouths as household words," manifested the interest which *it then excited, and which (agreeably to the general* law) has since been followed by a corresponding degree of neglect. That which is true of the science as a whole is also true of its various departments; and we have only to cite mineralogy as an example in order to show, that the ardour with which a subject may be pursued is strictly in proportion to its infancy, and that all sciences will be more and more neglected as they approach nearer and nearer to perfection, for it is the nature of men to endeavour to distinguish or enrich themselves. That mine will be most worked from which the greatest quantity of ore can be extracted; and that stream will be most frequented by anglers which most abounds with fish. This disposition, or fashionable mania, is far from being confined to philosophy or the arts, for in our own profession the same disposition to simultaneous movements obviously obtains, and particular diseases have particular æras in which they are cultivated with more than usual ardour, just as *epidemic* book-making among the profession always marches in the rear of pestilential visitations. But the extent of an evil is not to be inferred from the number of individuals who may sound the alarm; or, in other words, because a host of professional writers may start up at once, like the soldiers of CADMUS, it must not be inferred that the particular disease upon which they may choose to exercise their talents is therefore making dreadful, or more than ordinary, havoc amongst us, any more than that the downfall of our ecclesiastical establishments may be predicated from the senseless cry of "the church is in danger." Not long since nothing but consumptive maladies occupied the attention of the profession, and cart loads of books were written on the subject. Now, however, although the evil remains unmitigated and unarrested, that "song has ceased," and *spinal distortions* are become the reigning topic of the day.[1]

BATTLE OF THE CLUBS.

MEDICAL MEN AND FRIENDLY SOCIETIES: THE MEDICAL ACTS AMENDMENT BILL.

AT the Oddfellows annual moveable committee, held in Cheltenham last week, Bro. F. G. Green (South London) called attention to the introduction of the Medical Acts

---

[1] Extract from Review of books on Spinal Distortions by John Shaw, Surgeon and Lecturer on Anatomy; and R. W. Bampfield, Surgeon to the Royal Metropolitan Infirmary for Diseases of Children. London. 1824. Longmans and Co.

Amendment Bill which was down for second reading in the House of Commons and underlying which, it was contended, there was an attempt on the part of the General Medical Council to place a very severe embargo on those medical practitioners who undertook contract work for medical associations connected with friendly societies. He said that it appeared to be the intention of the Council to endeavour to get placed on the Statute-book a measure giving it the power to withhold the diplomas and to remove the names of medical men from the Medical Register who undertook work at contract prices for medical clubs In his (Bro. Green's) locality they had had great difficulty with regard to medical men in this connexion and there it was that the "doctors' strike," as it was called, originated. That district had been the forerunner in regard to the promotion of the Bill to which exception was taken. The first clause in the "Bill to Amend the Medical Acts, 1858 to 1886," which was backed by Sir John Batty Tuke, Sir John Gorst, Mr. James Campbell, Sir Richard Jebb, Mr. Talbot, and Sir Michael Foster, read: "Where a person registered under the Medical Acts has been convicted in England or Ireland of any felony or misdemeanour, or in Scotland of any crime or offence, or has, after due inquiry, been judged by the General Council to have been guilty of infamous conduct in a professional respect, the General Council may, if it thinks fit, by order demand that the name of the person shall be, and remain, erased from the Medical Register," &c. Bro. Green said that the view was held in friendly society circles that the expression "infamous conduct in a professional respect" might, if the Bill became law, be applied by the Council to medical men in connexion with medical associations. He therefore moved:—

> That the Parliamentary agent be instructed to take the necessary steps with a view to opposing the Medical Acts Amendment Bill in the House of Commons.

Bro. A. Pinhorn (South London) seconded the motion. In the course of the discussion which ensued the view was held that brethren might do much good in their respective districts in the direction of guiding public opinion in opposition to the object which it was considered that the promoters of the Bill had in view. The motion was unanimously agreed to.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7738 births and 4145 deaths were registered during the week ending June 6th. The annual rate of mortality in these towns, which had been 15·4, 15·5, and 14·9 per 1000 in the three preceding weeks, further declined last week to 14·3 per 1000. In London the death-rate was 13·8 per 1000, while in the 75 other large towns it averaged 14·6 per 1000. The lowest death-rates in these towns were 6·4 in Walthamstow, 6·9 in Reading, 7·1 in Burton-on-Trent, 8·0 in Hornsey, 8·2 in Willesden, 8·8 in Bristol, and 9·0 in Southampton; the highest rates were 19·9 in Liverpool, 20·6 in Bury, 21·0 in Wigan, 21·3 in South Shields, 22·0 in Warrington, 22·6 in Handsworth, 22·8 in Preston, 23·4 in Rochdale, and 29·1 in Middlesbrough. The 4145 deaths in these towns last week included 397 which were referred to the principal infectious diseases, against 428, 461, and 434 in the three preceding weeks; of these 4145 deaths 136 resulted from measles, 99 from whooping-cough, 66 from diarrhœa, 40 from scarlet fever, 38 from diphtheria, 12 from "fever" (principally enteric), and six from small-pox. In Hornsey, Southampton, Derby, Stockport, St. Helen's, Rochdale, Huddersfield, Halifax, York, and ten other smaller towns no death from any of these infectious diseases was registered last week; while they caused the highest death-rates in West Ham, East Ham, Great Yarmouth, Wolverhampton, Nottingham, Wigan, and Middlesbrough. The greatest proportional mortality from measles occurred in East Ham, Wolverhampton, Coventry, Nottingham, Wigan, Bolton, Sheffield, and Middlesbrough, and from whooping-cough in Croydon, Preston, Merthyr Tydfil, and Swansea. The mortality from each of the other principal infectious diseases showed no marked excess in any of the large towns. Two deaths from small-pox occurred in Manchester and one each in Liverpool, Bradford, Gateshead, and Cardiff, but not one in any other of the 76 large towns. The Metropolitan Asylums hospitals contained 72 small-pox patients at the end of last week, against 60, 64, and 60 at the end of the three preceding weeks; 24 new cases were admitted during the week, against seven, 19, and 10 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital which had risen from 1662 to 1771 at the end of the eight preceding weeks, had further increased to 1785 on June 6th; 210 new cases were admitted during the week, against 236, 234, and 225 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 225, 182, and 186 in the three preceding weeks, declined again to 171 last week and were 90 below the number in the corresponding period of last year. The causes of 56, or 1·4 per cent., of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Nottingham, Salford, and in 52 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, St. Helen's, Warrington, Blackburn, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·0, 17·2, and 18·4 per 1000 in the three preceding weeks, declined again to 18·2 per 1000 during the week ending June 6th, but was 3·9 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·8 in Perth and 15·1 in Paisley to 18·8 in Greenock and 19·1 in Glasgow and in Edinburgh. The 596 deaths in these towns included 25 which were referred to whooping-cough, 18 to diarrhœa, nine to measles, seven to scarlet fever, four to diphtheria, and two to "fever," but not one to small-pox. In all, 65 deaths resulted from these principal infectious diseases last week, against 68, 51, and 70 in the three preceding weeks. These 65 deaths were equal to an annual rate of 2·0 per 1000, which was 0·6 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 25, 22, and 28 in the three preceding weeks, declined again last week to 25, of which 16 were occurred in Glasgow, five in Edinburgh, and three in Greenock. The deaths from diarrhœa, which had been 12, 16, and 18 in the three preceding weeks, were again 18 last week, and included six in Glasgow, six in Edinburgh, and five in Aberdeen. The fatal cases of measles, which had been six in each of the two preceding weeks, increased last week to nine, of which four were registered in Glasgow and four in Edinburgh. The deaths from scarlet fever, which had been one and six in the two preceding weeks, further rose to seven last week and included five in Glasgow. The fatal cases of diphtheria, which had been six, three, and five in the three preceding weeks, declined again last week to four, of which two were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 101, 102, and 114 in the three preceding weeks, declined again to 111 last week, and were slightly below the number in the corresponding period of last year. The causes of 23, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·3, 22·4, and 22·2 per 1000 in the three preceding weeks, rose again to 22·7 per 1000 during the week ending June 6th. During the past four weeks the death-rate has averaged 22·4 per 1000, the rates during the same period being 14·2 in London and 18·1 in Edinburgh. The 165 deaths of persons belonging to Dublin registered during the week under notice were four in excess of the number in the preceding week and included ten which were referred to the principal infectious diseases, against 15, 11, and seven in the three preceding weeks; of these three resulted from small-pox, three from "fever," two from measles, one from whooping-cough, and one from diarrhœa, but not one from scarlet fever or from diphtheria. These 10 deaths were equal to an annual rate of 1·4 per 1000, the death-rates last week from the same diseases being 1·5 in London and 2·5 in Edinburgh. The deaths from small-pox, which had been four, four, four, and none in the four preceding weeks, rose again last week to three.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MAY, 1903.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1903.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small pox.	Measles. * Including membranous croup.

The fatal cases of "fever," which had been one, two, and one in the three preceding weeks, increased to three last week. The deaths from measles, which had been five, one, and none in the three preceding weeks, rose again last week to two. The mortality from both whooping-cough and diarrhœa showed a decline from that recorded in the preceding week. Seven inquest cases and four deaths from violence were registered, and 69, or more than two-fifths of the deaths occurred in public institutions. The causes of ten, or more than 6 per cent., of the deaths registered in Dublin last week were not certified. The 165 deaths in Dublin last week included 27 of children under one year of age and 47 of persons aged upwards of 60 years; the deaths of infants showed a slight decline, while those of elderly persons were considerably in excess of the number in the preceding week.

VITAL STATISTICS OF LONDON DURING MAY, 1903.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·0 per 1000 of the population, estimated at 4,613,812 persons in the middle of the year. In the three preceding months the rates had been 6·2, 5·9, and 5·4 per 1000 respectively. The rates were considerably below the average in Kensington, the City of Westminster, Hampstead, Stoke Newington, and Camberwell; while they showed the largest excess in Fulham, Chelsea, St. Marylebone, Deptford, Lewisham, and Woolwich. The prevalence of small-pox showed a slight increase over that recorded in the preceding month; of the 53 cases notified during May, 17 belonged to Battersea, ten to Poplar, and three each to Hackney, Southwark, Lambeth, Wandsworth, and Woolwich. The Metropolitan Asylums hospitals contained 60 small-pox patients at the end of last month, against five, 13, and 47 at the end of the three preceding months; the weekly admissions averaged 13 last month, against three, three, and 12 in the three preceding months. The prevalence of scarlet fever was slightly in excess of that recorded in any previous month of this year; among the various metropolitan boroughs this disease was proportionally most prevalent in Chelsea, St. Marylebone, City of London, Wandsworth, Deptford, Lewisham, and Woolwich. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1820, 1704, and 1685 at the end of the three preceding months, had risen again to 1738 at the end of May; the weekly admissions averaged 226, against 205, 208, and 201 in the three preceding months. Diphtheria was slightly more prevalent during the month under notice than in the preceding month; the greatest proportional prevalence of this disease occurred in Fulham, St. Marylebone, St. Pancras, Poplar, Deptford, Lewisham, and Woolwich. There were 808 cases of diphtheria under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1030, 903, and 760 at the end of the three preceding months; the weekly admissions averaged 120, against 152, 126, and 105 in the three preceding months. The prevalence of enteric fever showed a marked increase last month as compared with the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Kensington, Chelsea, Holborn, Lambeth, and Bermondsey. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 125, 92, and 53 at the end of the three preceding months, had further declined to 51 at the end of last month; the weekly admissions averaged 10 last month, against 13, 15, and five in the three preceding months. Erysipelas was proportionally most prevalent in Hammersmith, Chelsea, St. Pancras, Hackney, Holborn, and Camberwell. The 22 cases of puerperal fever notified during the month included three in Islington, three in Lambeth, two in the City of Westminster, and two in Southwark.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending May 30th the deaths of 5010 persons belonging to London were registered, equal to an annual rate of 14·2 per 1000, against 16·5, 15·9, and 15·8 per 1000 respectively in the three preceding months. The lowest death-rates last month in the several metropolitan boroughs were 9·8 in Hampstead, 10·5 in Kensington, 10·7 in Lewisham, and 11·3 in Fulham, in Stoke Newington, and in Wandsworth; while the highest rates were 16·5 in Holborn, 16·6 in Shoreditch and in Battersea, 17·6 in Poplar, 18·8 in Southwark, and 19·1 in Finsbury. The 5010 deaths from all causes included 550 which were referred to the principal infectious diseases; of these, one resulted from small-pox, 244 from measles, 33 from scarlet fever, 48 from diphtheria, 136 from whooping-cough, 15 from enteric fever, and 73 from diarrhœa. The lowest death-rates from these infectious diseases last month were recorded in Kensington, City of Westminster, Hampstead, Stoke Newington, Camberwell, and Lewisham; and the highest rates in St. Pancras, Holborn, Finsbury, Shoreditch, Poplar, and Battersea. The 244 deaths from measles were 23 below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in St. Pancras, Hackney, Finsbury, Shoreditch, Bethnal Green, Poplar, and Battersea. The 33 fatal cases of scarlet fever showed a decline of 21 from the average number in the corresponding periods of the ten preceding years; the greatest proportional mortality from this disease occurred in St. Marylebone, Holborn, Finsbury, Bermondsey, and Woolwich. The 48 deaths from diphtheria were only one third of the corrected average number; this disease was proportionally most fatal in St. Marylebone, St. Pancras, Holborn, Shoreditch, Poplar, and Bermondsey. The 136 fatal cases of whooping-cough showed a decline of 68 from the average number in the corresponding periods of the ten preceding years; among the various metropolitan boroughs the greatest proportional mortality from this disease was recorded in Paddington, Fulham, Chelsea, Islington, Finsbury, Poplar, and Southwark. The 15 deaths from enteric fever were 14 below the corrected average number; this disease showed the highest proportional fatality in Chelsea, City of Westminster, Stoke Newington, and Lambeth. The 73 fatal cases of diarrhœa were 14 in excess of the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Hammersmith, Holborn, Stepney, Poplar, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was nearly 19 per cent. below the average.

Infant mortality in London during May, measured by the proportion of deaths among children under one year of age to registered births, was equal to 98 per 1000. The lowest rates of infant mortality were recorded in Fulham, St. Marylebone, Hampstead, Bethnal Green, Stepney, Wandsworth, and Lewisham, and the highest rates in Hammersmith, Chelsea, the City of London, Southwark, Lambeth, and Battersea.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following Staff Surgeons have been promoted for conspicuous professional merit to the rank of Fleet Surgeon in His Majesty's Fleet:—Edward Bridges Townsend and Patrick Brodie Handyside. Dated May 30th, 1903.

The following appointments are notified:—Surgeons: W. E. Ruttledge to the *Robin*, C. A. G. Phipps to the *Edgar*, R. W. B. Hall to the *Bramble*, and W. W. Keir to the *Britomart*.

ROYAL ARMY MEDICAL CORPS.

Major F. S. Heuston, C.M.G., is seconded whilst holding the position of Physician and Surgeon to the Royal Hospital, Kilmainham. Dated Oct. 1st, 1902. Lieutenant-Colonel A. W. P. Inman, from the seconded list, to be Lieutenant-Colonel. Dated Oct. 1st, 1902. Lieutenant-Colonel J. A. Gormley is placed on retired pay. Dated June 3rd, 1903.

IMPERIAL YEOMANRY.

Staffordshire (Queen's Own Royal Regiment): Surgeon-Captain E. W. Welchman to be Surgeon-Major. Dated June 6th, 1903.

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 4th West Riding of Yorkshire: Surgeon Lieutenant A. W. Cuff to be Surgeon-Captain. Dated May 9th, 1903.

Rifle: 1st Volunteer Battalion the Royal Warwickshire Regiment: Surgeon-Captain R. A. Newton to be Surgeon-Major. Dated June 6th, 1903. 4th Volunteer Battalion the South Wales Borderers: William Percival Miles to be Surgeon-Lieutenant. Dated June 6th, 1903. 3rd Volunteer Battalion the Gloucestershire Regiment: Surgeon-Lieutenant T. M. Carter resigns his commission and is appointed Lieutenant. Dated June 6th, 1903 3rd Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Surgeon-Lieutenant A. Waugh resigns his commission. Dated June 6th, 1903. 1st Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment): Surgeon-Lieutenant E. V. Eames to be Surgeon-Captain. Dated June 6th, 1903 1st Volunteer Battalion the Loyal North Lancashire Regiment: Surgeon-Lieutenant J. Lea resigns his commission. Dated June 6th, 1903.

Mentioned in Despatches: the Darwesh Khel Waziris Operations.

In a despatch from Major-General Sir C. C. Egerton, K.C.B., D.S.O., published in the *London Gazette* of June 5th and dated May 28th, the name of Colonel J. T. B. Bookey, C.B., I.M.S., is mentioned, "to whose power of organisation is due the success of the medical arrangements for the force."

The Annual Dinner of the Royal Army Medical Corps Militia.

This dinner was held on June 8th in the Alexandra Hall of the *Trocadéro* Restaurant, Piccadilly-circus, London, W. The chair was taken by Sir Frederick Treves, Bart., K.C.V.O., C.B., and among the guests entertained by Colonel Sir J. R. A. Clark, Bart., C.B., and the officers of the Royal Army Medical Corps Militia were Major-General Sir W. Gatacre, Sir John Furley, Sir William Taylor, K.C.B. (the Director-General of the Army Medical Service), Major-General Sir A. Turner, K.C.B., Lieutenant-Colonel W. Babtie, V.C., C.M.G., R.A.M.C., and Surgeon-General A. H. Keogh, C.B., R.A.M.C. The toast of "The Services" was proposed by Sir J. R. A. Clark, who said they were all confident that the services would work together with that unanimity and single-heartedness of purpose for the welfare of the empire which could alone secure success. Major-General Sir W. Gatacre, in reply, said that the combatant forces could not take their part in the work allotted to them without the help of the medical services. They had a valuable body in the Royal Army Medical Corps Militia and they all hoped that that branch would increase and multiply and always attract the best men to its ranks. Major-General Sir A. Turner, who also replied to the toast, said that in regard to the auxiliary forces the nation must depend on voluntary efforts and the late war had shown that they could depend on the auxiliary forces with confidence. He looked on the Army Medical Department as equal in importance to any department, for it contended in the field with disease which claimed far more victims than the sword or bullet and last, but not least, it alleviated suffering and secured the means of health. Sir William Taylor also acknowledged the toast and congratulated the Royal Army Medical Corps Militia on the promotion of Sir J. R. A. Clark to his full rank as colonel. Major Moyle O'Connor, R.A.M.C. (Militia) then proposed "The Guests" and said that it would encourage men to join the Royal Army Medical Corps Militia when the fact was known that it had been stated by Sir William Taylor and by Mr. Brodrick that they were to have a preferential claim when officers of the Royal Army Medical Corps were not available for any particular service. That would be a good point to put before candidates for the Royal Army Medical Corps Militia. The toast was replied to by Major-General W. S. Oliphant who complimented his hosts on the keenness and ability with which they did their duty. Sir John Furley also responded.

The Question of the Infected Army Blankets.

While no one would hold Mr. Brodrick, or the department over which he presides, as in any way directly responsible in the matter of the infected army blankets it must be admitted that he was placed in a very disagreeable and awkward position in having to explain what he did not seek to justify—namely, the blundering and reprehensible course which had been adopted by the authorities at Cape Town. Apart even from the regulations which exist on the subject and the instructions which had been expressly issued from the War Office in regard to the method of dealing with the infected bedding and stores in South Africa, we should have thought that common sense and prudence would have suggested that something more than ordinary care was required in dealing with enormous "stacks" of soiled and infected blankets. Admitting that the conditions set forth by Mr. Brodrick were of a pressing and exceptional character they really afford no justification for what was done and it is very unsatisfactory to the British public to be merely told that "the military authorities are considering the matter." In view of rendering any such occurrence as that which took place in South Africa impossible in future it seems to us that the War Office might go further than it has done. It should insist upon the thorough disinfection of all infected and soiled blankets and other articles as an invariable practice (where they are not ordered to be burned) and [illegible] bit the sale or other dis- [illegible] It will be remembered [illegible] exhaustive inquiry instituted [illegible] ment into the causes of "the [illegible] volunteer camps of the Unite [illegible] only was there direct infection from man to man, but the indirect infection from contaminated clothing, bedding, and tentage was very forcibly dwelt upon and worked out in connexion with what the American commission called "company epidemics."

The Dinner of the South African Civil Surgeons.

Sir William Thomson, C.B., presided over this dinner which was held on June 5th at the Hotel Cecil. Mr. Clinton T. Dent, in proposing the toast of "The Imperial Forces," observed that "Tommy Atkins" in the South African war had by his cheery good humour and dogged endurance made himself everyone's friend. Referring to the soldier's remarkable propensity for recovery from the severest operations of every kind he said that this quality endeared him to the gentlemen who had to submit him to such inconvenience. The Imperial forces included men of every creed and colour knit into close union in the time of war but apt to become a little loosely divided in time of peace. To render the union more permanent was a matter for the practical politician. It had to be recognised that in time of national trouble it would be absolutely necessary to call on civil help to aid the military forces and it seemed to him that it was a pity that no attempt was made to organise in time of peace the civil medical community so that help could be afforded in time of need. Surgeon-General A. H. Keogh, C.B., R.A.M.C., replied to the toast and said that he was glad that the civil portion of the medical community had recognised its duty to the army in time of war because in future campaigns of any magnitude the civil medical element would undoubtedly have to be relied upon. The civil medical profession should therefore be organised in time of peace in order that it should be able to render efficient aid when necessary. The company separated after the chairman's health had been proposed by Mr. G. H. Makins, C.B., and suitably acknowledged.

The residential part of the Royal Army Medical College has been removed from the Hotel Belgravia to St. Ermin's Hotel, Westminster.

Correspondence.

"Audi alteram partem."

ASEPTIC AND ANTISEPTIC SURGERY.

To the Editors of THE LANCET.

SIRS,—Surely Mr. W. Watson Cheyne's remarks in his paper read before the Harveian Society were not meant to lead to a criticism of the general practitioner. He referred to the surgeons who practise aseptic as distinguished from antiseptic surgery. I must most strongly protest against Mr. F. Deane's endeavour to belittle the "general practitioner" and to dictate to him what he should do.[1] Surely a general practitioner, more especially the younger members, after being schooled in the practice of antiseptic surgery, can often be as sure of obtaining primary union as the consultant and that without stitch abscesses. I myself do all my own operations and carrying out the precautions and directions given in Lockwood's "Aseptic Surgery" have obtained primary union in all cases—e.g., removal of adenoma from the breast, radical cure of hydrocele and hernia, removal of tuberculous glands in the neck, removal of dermoids over the eye, &c. What more could any surgeon obtain? This belittling of the general practitioner leads to such a state of affairs as the following. A general practitioner is called to see a patient who has fractured the greater tuberosity of the humerus. The general practitioner informs his patient that his arm is broken and the patient at once says that he must have the best man down from London. A consultant comes down, the patient has an anæsthetic, his arm is examined, and the diagnosis is confirmed. Of course, the result is that much more effusion is thrown out which has to be got rid of by massage, &c., and the consultant pockets a fee of 10, 20, or more guineas, practically for doing what was absolutely unnecessary and yet never sees the patient again. All the hard work and important massage, &c., have to be done by the general practitioner with the result of a good useful arm.

---

[1] THE LANCET, May 30th, 1903, p. 1543.

Surely, if a general practitioner is enthusiastic over surgery and will take endless pains to get all his instruments, dressings, sutures, &c., absolutely sterile and can be absolutely sure of primary union, why should he not attempt it? There are so many people who cannot afford a consultant's fee for operation and yet do not care to go into a hospital. Why should not the general practitioner take a smaller fee and give the patient as much satisfaction as if the operation were done in a hospital? The whole crux of the question, aseptic *v.* antiseptic surgery, is this, You cannot possibly do without using antiseptics and the best results, whether in hospital or private practice, are obtained by combination of both heat and chemicals as mentioned by both Mr. Watson Cheyne and Mr. C. B. Lockwood.

I am, Sirs, yours faithfully,

London, June 3rd, 1903. ROBERT HENDERSON.

SPITTING IN PUBLIC-HOUSES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 16th, p. 1401, Dr. Sidney Davies refers to public-houses as being fruitful sources of phthisis. Allow me to emphasise his remarks by drawing attention to another aspect of the same subject. There is a widely spread custom, especially in old inns, of using spittoons containing sand, sawdust, malt-dust, &c., which are dealt with in ways more or less insanitary. A few days ago while cycling I experienced an object lesson not easily forgotten. Outside a charming old inn was arranged a row of wooden spittoons. These, with their filthy contents, were placed on benches in the sun to dry and after a superficial sprinkling of sawdust were replaced in the bar, &c. Such a condition is doubtless the result of ignorance and very simple measures need be taken to correct such misuse of the spittoon method of dealing with expectoration.

I am, Sirs, yours faithfully,

Devonshire street, W., June 4th, 1903. WYATT WINGRAVE.

THE DIRTY FOUNTAINS IN TRAFALGAR-SQUARE.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to say a few words on this from the point of view of the design of such spaces in cities? For years I have seen these huge and ugly basins with regret and put down to our British toleration of ugliness that the most used of any open space in London should be so degraded. Apart from the filth of the water the square is wholly wrong from the point of view of good and simple design. If we are to have such breathing spaces in crowded cities surely it is only plain reason to ask that they be not merely to add to the areas of asphalte and stony surfaces with which we are already amply supplied? The mistaken idea of these huge fountain basins is taken from cities like Rome with a long and hot summer. Fresh and delicious water coming from the hills and tumbling into the hot places of Rome, supplying the people with water and cooling the hot streets, was a necessity, and Roman artists made their fountains worthy of their great use and of the city of Rome. But in our cool and moist country there is no need, artistic or other, for the introduction of huge water-basins of this character and we may see the hideous result in other places as well as Trafalgar-square—for example, the head of the Serpentine.

On the other hand, we have evidence, both in London and other cities, that such small places may be fresh and beautiful, even in the smoke. There is surely enough work for our architects to rebuild our houses and cities without despoiling open spaces which with a little thought and care might add to the beauty of the town. Even their own true work suffers as such "architectural gardening," as it is called, offers no relief to buildings as even poorly planted squares do. The spaces about Trafalgar-square are so wide and airy that there is not the slightest occasion to leave a wide spread of asphalte towards the middle. There might be two lines of trees on the upper terrace and the tramps who now defile the whole place should be kept to that or some other fixed place and not occupy, as they do, the best place in the square. The warm side would be a happy place to grow the flowers that in our climate enjoy and need the sun. Even without any great change of plan the great basins would form noble flower-beds, but the best and most dignified way would be to make a clearance of the whole central block of asphalte, &c., and plant trees and shrubs. Let anyone who looks at this square in its present state go and look at some of the smaller squares in the West Central district and then compare the effect. The gardening in the squares of London is the worst of any city in Europe—men digging and muddling about overgrown privet and like rubbish—yet the trees save the situation as they would Trafalgar-square. The effect need not be in any doubt, because we have plenty of evidence already that trees that thrive in London may adorn such places.—I am, Sirs, yours faithfully,

Lincoln's Inn-fields, June 8th, 1903. W. ROBINSON.

THE USE OF THE SINGLE CUP AT THE CELEBRATION OF HOLY COMMUNION.

To the Editors of THE LANCET.

SIRS,—In view of the interest which this subject is awakening and for purposes of information in a forthcoming local discussion on the subject I should be glad if any of your readers who have been able to trace the spread of disease to the promiscuous use of one cup at the celebration of Holy Communion would kindly place a record of their experience at the disposal of the public. I venture to think that there is a strong *primâ-facie* case against the use of one cup, but the task of the hygienic innovator would be made much easier if he could cite actual examples of contagion.

I am, Sirs, yours faithfully,

Rochdale, June 9th, 1903. J. H. BRITTAIN.

PENAL CASES AT THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—Reading the report of the meeting of the General Medical Council in THE LANCET of last week I notice that at least two of the cases before the Council of charges of infamous conduct were adjudged not proven against the supposed offenders and the President, in delivering judgment did not even caution these gentlemen, so that one may assume that the charges completely fell to the ground. I do not know precisely who or what person or body in either case was answerable for these gentlemen appearing before the Council, but it is quite evident that some person or persons outside of the Council must have laid these charges for the Council to adjudicate upon and that each of these practitioners must have been put to considerable expense to refute them, that they must have suffered great mental worry and been caused much trouble. There will be also in the minds of a great many a stigma attached to the names of these gentlemen which it will take some time to efface.

I want to ask, therefore, in the interests of the whole profession, if either, or both of these gentlemen, having been declared innocent of the charges made against them, has any redress? Can they ascertain who was responsible for the prosecution (or shall I say persecution?) and go for damages in the civil court for defamation of character? It is evident that if charges can be made to the Council by any irresponsible person no member of the profession is safe. I am sorry to take up your valuable space but I think that this is a matter of great importance in the light of your report of the meeting of the Council last week.

I am, Sirs, yours faithfully,
THOMAS MARSHALL, L.R.C.P. & S. Edin.,
London, June 1st, 1903. L.F.P. & S. Glasg.

*** Our correspondent raises a most important question and one upon which no off-hand opinion can be expressed. He is wrong, surely, in believing that a practitioner accused before the General Medical Council of professional offences remains in ignorance of the name of his accuser.—ED. L.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Physical Unfitness of Volunteers in India.—The Plague Epidemic.—Nursing Arrangements at the Jamsetjee Jeejeebhoy Hospital.

THE physical defects which would incapacitate so many of the volunteers at home from active service appear to be still more marked among the volunteers in India. The 800 unmounted volunteers who were at the Delhi durbar afforded to Surgeon-Lieutenant-Colonel J. S. Brooke an opportunity of showing in his report various particulars of the general physical condition of the men under his charge. In all 333 men came on sick parade—a very large proportion out of 800 considering the short time during which they were on duty and the fact that their work was almost entirely ceremonial. 14 were sent home as totally unfit for any service. Surgeon-Lieutenant-Colonel Brooke says that the extremel [illegible] volunteers confirms him in [illegible] lunteers should be medically examined before being enrolled. He has no hesitation in saying that on field service fully 35 per cent. of the men at Delhi would have been useless. In this connexion [illegible] red that the volunteers [illegible] n of mixed blood—in [illegible] ıe corps there is very [illegible] the natives, and even that in many cases typical natives have been admitted. This is a serious question, because the volunteers in India are more likely to be called upon for duty than are those at home and physical unfitness in so large a proportion would cause us to live (if the volunteers here are to be of any use) in a fool's paradise. There are very few corps solely composed of men of pure British blood and these are the few crack corps in the country.

The mortality returns for Bombay city are now rapidly returning to a more normal standard. The deaths from plague have rapidly declined in number during the past few weeks, [illegible] these fluctuating records are the fruit of inaccurate registration. Plague seems, as it were, to leave Bombay by the north of the island as, while declining in the city, it attacks the villages to the north very severely. The epidemic of plague throughout India has been the subject of some general influence. The outbreaks in various places have declined rapidly during the past few weeks and although Karachi is still badly affected, as are some parts of the Punjab, the disease is everywhere else subsiding. Very little inoculation work is being done for plague, still less for cholera, and that for typhoid fever is now, for the army at any rate, prohibited.

I reported to [illegible] state of the nursing [illegible] and adjoining h[illegible] wards of the Jamsetjee Jeejeebhoy Hospital, which were nearly always full, were the patients nursed at all, the remainder being left to the tender mercies of ward boys and ayahs. Mr. and Mrs. Crowe took up the task of improving this condition of things and a large sum of money has been collected. The nursing fund will now with Government help be very little short of its requirements, but the nurses' quarters being very badly wanted Mrs. Wadia (a wealthy Parsee lady) has undertaken to build them. A serious reproach to the present generation of Bombay citizens has thus been completely removed.

May 23rd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital: Endowment of a Bed by a Football Club.

THE famous Aston Villa Football Club is well known to all persons taking any interest in a sport which attracts the attention of so many during a large portion of each year. It will, however, be news to most that, in addition to taking a high place in the world of athletics, this club gives considerable sums in aid of charities of various kinds, the sum actually contributed during the past 11 years amounting to about £20,000. The last exhibition of its generosity took place on June 5th, when a cheque for £1250 was handed over to the committee of the General Hospital for the permanent endowment of a bed in the accident ward of that hospital. The history of the raising of this sum is of interest. In 1899 Mr. Margoschis, who had long been one of the directors of the club, retired from that position and in order to mark its sense of the services which he had rendered it was decided to present him with a sum of £100. Mr. Margoschis, instead of accepting the gift for himself, expressed a wish that it should form the nucleus of a fund to be raised permanently to endow a bed in the hospital. The result of many efforts during the past four years has been that the sum has now been raised and a deputation from the club was present at the meeting of the committee of the hospital held last week when a cheque, as above stated, was handed to Mr. Hugh Smith, the chairman of the committee, by Mr. Margoschis himself.

Education Committee.

In a previous letter I mentioned that the education committee had advertised for a superintendent of special schools who might either be a medical woman or a person with special knowledge of this particular class of schools and I expressed the hope that a member of the medical profession might be selected for this post. At the last meeting of the committee this hope was realised by the appointment of Miss Caroline E. O'Connor, M.B., Ch.B. Edin., at a commencing salary of £150 per annum. In proposing her election, Mrs. Pinsent, who is chairman of the subcommittee charged with the care of these schools, said that a few years ago it was supposed that there were comparatively few children in Birmingham who could be regarded as mentally deficient. Inquiries, however, revealed the fact that there were many mentally defective children in the schools whose presence therein had not been generally known. It was estimated that whilst there were between 8000 and 9000 such children in London there were between 800 and 900 in Birmingham. At the end of April, 1902, only 118 were on the register of special classes in this city and it became apparent to the late school board that every effort must be made to trace out the children of this class who were in the ordinary schools. The duties of superintendent were undertaken by the members of the committee but it soon became evident that a special officer must be appointed to take charge of this work; hence the appointment which has just been made. Dr. O'Connor was for some time medical officer of Eday, one of the Orkney islands.

Health of Birmingham during 1902.

The last report—that for the year 1902—which the present medical officer of health, Dr. Alfred Hill, will issue has recently been made public. From this it appears that the death-rate during the past year is the lowest that has ever been recorded in Birmingham and that, as regards the sanitary condition of the city, considerable advance has been made in different dir[illegible] The estimated population of the city was 528,521 a[illegible] ses was about 110,500. The [illegible] r were equal to a birth-rate [illegible] ılation. This is a very low figure, in fact, only once—viz., in 1894, when the birth-rate fell to 31·6—has such a small ratio been recorded. The number of marriages registered was 5120, equal to a rate of 19·1 per 1000. The death-rate was 18·0, this being 2·2 per 1000 below the average of the past ten years. If the rate had been the same as the average of the past ten years—20·2 per 1000—there would have been 10,844 deaths, whereas the actual number was 9672, a saving of 1172 lives. Dr. Hill calls attention to the great mortality amongst infants which he states is more than ten times as great as that of the population as a whole. Last year, however, the infantile mortality of Birmingham was unusually low, being at the rate of 157 infant deaths per 1000 births, against an average of 189 in the previous ten years. The deaths from the seven principal zymotic diseases numbered 1397, equivalent to a death-rate of 2·6 per 1000. The deaths were thus divided: diarrhœa, 412; scarlet fever, 293; whooping-cough, 269; measles, 189; diphtheria, 130; enteric fever, 100; and small pox, 4. There were notified during the year 5044 cases of scarlet fever, 787 of diphtheria, 544 of enteric fever, 69 of small-pox, and 1548 of chicken-pox. Dr. Hill calls special attention to the value of vaccination and revaccination and insists that it is only since vaccination became more general that small-pox has taken the mild and not very fatal form with which we are now acquainted. The number of cases of scarlet fever was far greater than in any other year since compulsory notification was introduced. The deaths, however, were not very numerous, amounting only to 5·8 per cent. of the cases. During the year there was an increase in the number of cases of diphtheria from 533 to 787 and there were 130 deaths as compared with 85 in the former year. Dr. Hill thinks that the increase in this particular kind of disease is in some way connected with the great prevalence of scarlet fever. From consumption there were 874 deaths and from other forms of tuberculosis there were 219, giving, for cases of consumption, a death rate of 1·63 per 1000. The death-rates, as on previous occasions, show that consumption is principally a disease of the less sanitary portions of the city, where both the hygienic and social conditions are of an inferior character. The number of houses declared to be unfit for human habitation by the medical officer during the year was 450 and all these are being dealt with by the health committee. The report also contains a statement of the number of cases in which sanitary improvements were insisted upon and carried out during the year.

June 9th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The New University of Liverpool.

THE clerk of the Privy Council has issued the draft charter incorporating the University of Liverpool. One of the conditions of the constitution of the University is that there shall be no religious tests imposed on either teachers or students and that no theological teaching shall be given by, or under the authority of, the University. Colleges and institutions in which theological teaching is given may, however, be recognised by affiliation. Women are to be eligible for any office in the University and for membership of any of its constituent bodies, and all degrees and courses of study in the University are to be open to women, subject to such conditions and regulations as the statutes of the University may prescribe. The court will include, in addition to members of the University, five persons appointed by the city council, one by the House of Keys of the Isle of Man, two by the county council of Lancashire, one each by the counties of Cheshire, Cumberland, Shropshire, and Westmorland, one each by the boroughs of Barrow-in-Furness, Birkenhead, Bootle, Chester, Crewe, Lancaster, Leigh, Preston, St. Helen's, Southport, Warrington Widnes, and Wigan, and one by the district councils of Runcorn and Wallasey, the Members of Parliament for Liverpool and Birkenhead, and not less than ten Members of Parliament for the boroughs and divisions of counties or boroughs in the counties of Lancaster and Cheshire to be nominated by the court, the Governor of the Isle of Man, the Lords Lieutenant of the counties of Lancaster and Cheshire, the Lord Mayor of Liverpool, the chairmen of the Lancashire and Cheshire county councils, the Vice-Chancellor of the Duchy of Lancaster, the Bishops of Liverpool, Chester, and Sodor and Man, the Roman Catholic Bishops of Liverpool and Shrewsbury, and representatives of the Presbyterian Church of England, of the Congregational Union, of the Wesleyan Methodist Church, of the Baptist Church, of the Presbyterian and Unitarian ministers, and various officials of public bodies in Liverpool, Lancashire, and Cheshire; also representatives of various educational institutions in these districts. The court will be the supreme governing body of the University but the executive will be a council; there will also be a senate which, subject to the control of the council, will regulate and superintend the education and discipline of the University. The senate is to consist of the vice-chancellor, the deans of all the faculties, all the professors of the University, and the librarian. Principal Dale of University College is nominated as the first vice-chancellor.

The Gradual Subsidence of Small-pox in Liverpool.

At the meeting of the health committee held on June 4th Dr. E. W. Hope, the medical officer of health, reported that 33 fresh cases of small-pox had been notified during the past week, as against 49 during the previous week. There were 198 cases in hospital, compared with 231 and 253 in the previous two weeks. The cases in hospital had decreased from 335 on March 19th to 198 on June 4th. There had been four deaths from small-pox during the week.

University College, Liverpool: New Lectureships.

The council of University College, Liverpool, has made the following appointments to lectureships in the faculty of medicine: Specific diseases, Dr. A. Bernard; experimental medicine, Dr. A. S. F. Grunbaum; and comparative pathology, Dr. H. E. Annett.

Meeting of the Anatomical Society in Liverpool.

The Anatomical Society will hold its summer meeting at University College, Liverpool, on June 19th and 20th. The programme is an interesting one and includes meetings for the exhibition of specimens and the reading of papers. Dr A. N. Walker is the local secretary of the society. The society's dinner will take place at the Adelphi Hotel on June 19th. The Manchester Edinburgh University Club has taken advantage of the meeting of the Anatomical Society at Liverpool to invite Sir William Turner and Professor D. J. Cunningham to a complimentary dinner at the Adelphi Hotel on June 18th. All Edinburgh graduates are invited to be present and may bring guests. Tickets (10*s* 6*d*. each, exclusive of wine) may be obtained from the local secretary, Dr. R. C. Dun, 6, Rodney-street, Liverpool.

The Health of Bootle: Mr. T. W. N. Barlow's Annual Report.

Mr. Barlow (the medical officer of health of Bootle) in his annual report for 1902 emphasises the protection afforded by vaccination and revaccination against small-pox. During the year there were 15 distinct outbreaks of small-pox—25 cases in all. Not one of the patients had been revaccinated and seven had never been vaccinated. There were four deaths and with the exception of one woman, aged 45 years, all were among the unvaccinated class. A further proof of the value of revaccination is afforded by the fact that while several of the nurses and ward-maids during the year had been attacked with scarlet fever, two with typhoid fever, one with diphtheria, and one with typhus fever, not one of the staff had contracted small-pox. All had been living under the same conditions and had been exposed to the same danger of contracting this disease as the others, but revaccination was insisted upon for every member of the hospital staff, with the result that not one had contracted the disease. Dr. Hope's experience at the Liverpool Small-pox Hospital coincides with that of Mr. Barlow, and it is inconceivable how the anti-vaccinationists can ignore such remarkable facts. The birth-rate of Bootle for 1902 is the highest recorded for six years. The death-rate was 18 9 per 1000 of the population. The zymotic death-rate was 2 7 per 1000. 46 children had died from measles; 14 had died from scarlet fever out of 321 cases notified. Infantile mortality, although still high, shows a gratifying decline, as also does the number of deaths from summer diarrhœa. The appointment of a veterinary inspector to inspect periodically the cattle in shippons has been attended by distinctly beneficial results. The health committee has agreed to Mr. Barlow's recommendation to remove the small-pox hospital to an isolated place further in the country.

June 9th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Monmouthshire Western Valley Sewer.

THERE appears to be at last some prospect of a trunk sewer being constructed for the drainage of those rapidly increasing colliery districts which now pollute the river Ebbw. A committee of the House of Commons has found proved the preamble of a Bill which provides for the construction within the next seven years of a sewer discharging into the Bristol Channel near Newport. The localities concerned are the urban districts of Ebbw Vale, Nantyglo and Blaina, Abertillery, Abercarn, and Risca which have a combined area of 31,000 acres, a population of 81,000, and a rateable value of £266,000. The population in 1891 was 69,000. The estimated cost of the sewer is £237,000. A great deal of contradictory evidence was given before the committee with regard to the relative advantages of a joint trunk sewer and of separate bacterial schemes. The advocates of the latter insisted that a main trunk was not at all suitable for a mining district where subsidences so often take place, but in opposition to this view evidence of the stability of the Rhondda sewer was tendered showing that this main trunk, which is 17½ miles long and cost £156,000 to construct, has quite fulfilled the expectations of its designers since it was completed in 1893.

Merthyr Tydfil Union Infirmary.

The board of guardians of the Merthyr Tydfil Union is very desirous of continuing the workhouse infirmary as a training school for nurses and the medical officer (Mr. J. L. W. Ward) has recently reported to the Local Government Board in some detail pointing out that the infirmary contains all the essentials of a training school, as set out in the report of the departmental committee on workhouse nursing, except that there is no resident medical officer—an omission which is practically met by the fact that he lives within a few minutes' walk of the institution and is in direct telephonic communication with every block and charge nurse The building is well equipped as a modern hospital, with an excellent operating theatre, and there is an x-ray apparatus for diagnostic and other purposes. During last year nearly 1200 patients were under treatment in the infirmary.

Vaccination of Vagrants.

In February of the present year the Leominster board of guardians instructed the medical officer of the workhouse to vaccinate all vagrants who were willing to undergo the operation and nearly 450 persons have thus been vaccinated. In view of the near approach of the hop-picking season, when several thousand men, women, and children come into Herefordshire from Staffordshire and South Wales, it is to be regretted that the board should have decided to rescind the resolution which it adopted in February. The reason given by the chairman of the board for taking this retrograde step is that it was anticipated that tramps would be kept away from the union, whereas there has actually been no diminution in the number seeking admission to the casual wards. It is only fair to state that all the members of the board are not in agreement with the chairman and one guardian pointed out that the single case of small-pox which had occurred this year among the tramps who visited the Leominster workhouse had cost the board £40.

Chippenham Cottage Hospital.

Although the Chippenham Cottage Hospital was established as recently as 1899 with eight beds it has already been found necessary to increase the accommodation and on June 2nd Lady Dickson-Poynder formally opened a new wing which includes a ward with a nurses' duty room and bedroom and a bath-room. The cost of these additions, including the furnishing, is £750 and nearly the whole of this sum has already been raised.

An Isolation Hospital in the Gower Peninsula.

Isolation hospitals are being gradually provided throughout Glamorganshire in response to pressure brought to bear by the county council. From the Gower rural district, where there is a decreasing population of about 7000 persons, small-pox patients have hitherto been received into the Swansea Hospital and the district council has persistently refused to establish an isolation hospital within its own area. The sanitary committee of the county council has therefore decided to make a compulsory order for the erection of a hospital.

Western Counties Asylum, Starcross.

The annual meeting of the subscribers to the Western Counties Asylum for the Treatment of the Feeble-minded was held at Starcross, Devon, on May 30th. The financial statement showed that the total income, including a favourable balance of £1070 brought forward from 1901, was £9229. The total expenditure was £8701 and a favourable balance of £528 remained. The medical report stated that during 1902 the average number of patients was 270, the health of the inmates had been good, and only one death had occurred. There had been an increase in the average cost of maintenance, which was 10*s.* 2*d.* per head, against 9*s.* 7d. in 1901. In these circumstances the committee has decided to raise the charge for cases from the four western counties from 9*s.* to 10*s.* 6*d.* weekly and for those from other counties to 14*s.* weekly.

June 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The University of Dublin.

THE Senate of the University of Dublin decided on June 9th to admit women to its degrees.

Royal College of Surgeons in Ireland.

A meeting of the Fellows of the Royal College of Surgeons in Ireland was held on May 30th to elect a President, Vice-President, council, and secretary of the College for the ensuing year. The following were elected:—President: Mr. L. Hepenstal Ormsby. Vice-President: Mr. Arthur Chance. Secretary of the College: Sir Charles A. Cameron, C.B. Council: Sir Philip Crampton Smyly, Mr. Henry Rosborough Swanzy, Mr. Edward Hallaran Bennett, Mr. William Stoker, Sir Charles Alexander Cameron, C.B., Mr. Austin Meldon, D.L., Mr. John B. Story, Sir William Thomson, C.B., Sir Charles B. Ball, Sir Thomas Myles, Mr. John Lentaigne, Mr. Richard D. Purefoy, Mr. Henry G. Sherlock, Mr. R. Bolton M'Causland, Mr. Robert H. Woods, Mr. Thomas Donnelly, Mr. William Taylor, Mr. Edward H. Taylor, and Mr. G. Jameson Johnston. Members of the court of examiners are not eligible for seats on the Council.

Public Health of Dublin.

[illegible] in reference to the public health of Dublin are [illegible] ver, measles, whooping- [illegible] but small-pox, of which a [illegible] s now on the decrease and [illegible] originally infected area on [illegible] successful prosecutions of [illegible] ment of cases have resulted [illegible] s notified as suffering from small-pox has decreased week after week in the city. Professor E. J. McWeeney, pathologist to the Local Government Board, has recently made public in a lecture delivered on May 25th some interesting statistics which he obtained from the Registrar-General. As regards tuberculosis—which is on the increase in Ireland while being fairly successfully dealt with elsewhere—it appears that during the year 1902 that disease, which is not notifiable, caused 1736 deaths in [illegible] while all the infectious diseases g[illegible] nsible for only 924. In reference [illegible] opinion was expressed that suitable sites might be obtained either in the Dublin mountains or in the large grazing districts of the north-western portion of the county, the fact being that if a patient was placed in a suitable ambulance car—preferably motor—it did not affect him much whether the distance was two miles or ten. With regard to measles he remarked that Dublin had suffered from a severe epidemic with 392 deaths last year. Whooping-cough caused 69 deaths and scarlet fever 76 The statistics in reference to diphtheria are interesting, for that disease was almost unknown in Ireland 15 years ago. There were no less than 473 notifications last year with 85 deaths. The mortality for the previous ten years averaged 42, so that a marked increase of deaths from diphtheria has certainly occurred in the Dublin registration area of late years.

The Sanitation of Dublin.

The Commissioners of National Education in Ireland have recently issued a memorandum to the managers of national schools respecting what they term "the extremely unsatisfactory condition of many of the national schoolhouses in regard to repair and cleanliness." The memorandum goes on to enumerate in detail the "disgraceful state" in which many schoolhouses are kept in respect to sanitary arrangements, and calls upon the managers, unless they are prepared to take the risk of losing State aid altogether, to exercise systematic supervision over the school premises. It is rather late for the commissioners to investigate and to take action as regards this matter, for, although the inspectors of the Board have reported many times in reference to it, it has remained a sanitary disgrace to Ireland for years. The able inspector from THE LANCET, who came over to this country some years ago in order to investigate the causes of the high death-rate in Dublin, was surprised at the state of things as regards personal sanitation which prevailed here. He remarked that the poor people in Dublin even when perfect sanitary arrangements were available did not seem to know how to use them. There can be no doubt that the fault really lies with the managers of the national schools of Ireland and it is full time that the Board should proceed to institute a reform. One of the most experienced national school inspectors mentioned to me some time ago that the condition of the sanitary arrangements in his schools—many hundreds—was such that it would be far better if such premises were non-existent. The *Irish Times*, in a leading article on the subject, says:—

> It is to be hoped that the Commissioners of National Education, now that they have taken the matter in hand, will firmly insist on a systematic and satisfactory supervision of the school premises on the part of those who are locally responsible for their maintenance. In this course they will be firmly sustained by the public opinion of the country.

The Granard Nursing Scandal.

The nursing trouble at the Granard union has been temporarily settled. At a meeting of the board of guardians on June 1st Dr. Joseph Smyth, Local Government Board inspector, appeared and recommended that no action should be taken, in the hope that by removing certain defects in the nursing arrangements of the house the causes of official friction between the nun nurses and Dr. J. M. S. Kenny might be removed. After a protracted debate that course was adopted. The guardians promised to appoint a fully qualified nurse at a salary of £35, while the nursing nuns consented to stay on as nurses for another two weeks.

The Poor-law Medical Service in Ireland.

The casual reader of an Irish newspaper at the present moment must see from the constant references to disputes between medical men and the local and central authorities that matters cannot long go on as at present. References have already been made in THE LANCET[1] to the difference between Dr. E. C. Thompson, M.P., and the Omagh guardians. He demanded 12 guineas for his four days' attendance for Dr. H. B. Fleming (they had previously summarily dispensed with Dr. Thompson's services); they offered three guineas. On June 6th Dr. Thompson's solicitor sent a letter on his behalf to the effect that three guineas is the minimum fee fixed by the Irish Medical Association for a medical man who agrees to act for so small a fee and was never intended to apply to such a case as the one under discussion, nor to a practitioner of the standing of Dr. Thompson, nor did the guardians appear to take into consideration the fact that by their action they deprived Dr. Thompson of fees for the remainder of the time during which Dr. Fleming was unable to perform the duties. In these circumstances Dr. Thompson declined the offer of the guardians but was still open to accept a reasonable sum rather than to resort to a court of law. The guardians have decided to fight the case on its merits and it is hoped that Dr. Thompson will give them the chance. At the same board Mr. James Hamilton of Dromore wrote that he could get no substitute to act for him at the fee offered by the board and that he would therefore ask for no vacation at present; while Mr. Thomas Duncan, medical officer of the Fintona dispensary, wrote in reference to some disparaging remarks made by the guardians in reference to his fee for attending at Fintona petty sessions in a vaccination prosecution that he only did so on receiving an intimation from the public health committee in Dublin. A guardian said that this letter should be treated with contempt and thrown into the wastepaper basket—that is, a medical man who obeys the central controlling body in Dublin is censured by the local authorities in his own district. At a meeting of the Coleraine rural council on June 6th a letter was read from the Local Government Board in reference to a fee of £2 2*s.* due to Dr. J. Lennox, J.P., of Kilrea, for attending the Coleraine quarter sessions on behalf of the council, to the effect that in a case like this "the council might pay the medical officer concerned not less than one guinea and not more than two guineas." Naturally, the council after this oracular statement resolved to ask Dr. Lennox if he would accept one guinea, which it is to be hoped he will decline. It is most unfai to the medical officer to put him in this position, and obliges him him to fight the case, while the Loca Government Board should say when appealed to whethe he is entitled either to what he claims (£2 2*s.*) o to one guinea. It is this vacillating, hesitating polic which largely keeps up the present unpleasant frictio between the medical officers and the guardians. Again at a meeting of the Londonderry guardians on June 6th the clerk stated that the Local Government Board ha written sanctioning the payment of one guinea to Dr. F. A Craig for acting as substitute for Dr. James Craig dispensary officer, but had not replied whether the guardian could deduct that amount from the salary of Dr. Jame Craig, as it had been asked to do. These cases which have cited—and they are examples of what is now constantly occurring all over Ireland—show to what a pass w have come in medical matters in Ireland. The feeling i becoming stronger, even amongst moderate men, that befor long if their reasonable demands are not granted the whol of the medical dispensary officers of Ireland will resign e *masse*, relying on the rest of the profession in that country t support them in their struggle by not applying for thei posts.

The Poor-law in Ireland.

A viceregal commission, consisting of Mr. W. L. Mick one of the Commissioners on the Local Government Boar for Ireland (chairman), Mr. George Murnaghan, M.P. (chai man of the Omagh board of guardians) and Dr. E. O. Bigge medical inspector of the Local Government Board, has bee appointed by Lord Dudley to inquire into, and to report o the following subjects:—

1. Whether any Poor-law unions could be dissolved with advanta to the ratepayers and without hardship to the sick and destitute poo and if any such dissolution be deemed desirable what arrangements l amalgamation of unions or otherwise should be substituted therefor.
2. Whether, in the event of any unions being amalgamated and t workhouses thereof being no longer required for Poor-law purpose such workhouses could with advantage be taken over by count councils for auxiliary lunatic asylums under Section 76 of the Loc Government (Ireland) Act, 1898, or could be otherwise utilised for a public purpose.
3. Whether it would be possible, either by an arrangement for t maintenance of paupers in adjoining workhouses or by combining number of unions for the purposes of indoor relief, to make bett provision for the classification and treatment of the inmates, especial the aged and infirm sick, lunatics, and children chargeable to the sa unions, and whether any changes in the law and procedure as to t administration and chargeability of relief would be desirable in t event of such combination of unions being carried out.
4. Whether, having regard to the number and capacity of workhouse hospitals, and infirmaries existing in any county, union, district, locality, and to the other provisions for the relief of the sick poor, a additional accommodation is now required for the proper treatment the sick poor, and, if additional accommodation is necessary, how might best be provided.
5. Generally to inquire and report whether any and what administr tive and financial changes are desirable in order to secure a mo economical system for the relief of the sick, the insane, and all clas of destitute poor in Ireland, without impairing efficiency of admin tration.

Great surprise has been expressed in medical circles that r direct reference has been made for the consideration by th commission of the grievances of the medical officers und the Poor-law system and it is regarded as very extraordina that those responsible for drawing up the references ha paid no consideration to the present widespread feeling i Ireland on the question. The natural result will be that t combination plan will be pushed on, as neither from t central authority (the Local Government Board) nor fro the guardians can the Poor-law medical officers receive a fair consideration of their just claims. The profession h only to remain true to itself and the victory will soon be wo

Radioscopy in the Examination of Candidates for Life Assurance.

THE Third International Congress of Medical Officers of Life Assurance Companies was held in Paris from May 25th to 28th and gave rise to several interesting discussions, including one upon the radioscopic examination of candidates for life assurance. M. Béclère said that the [illegible]ine was the discovery of [illegible] inspection of the skeleton [illegible] to the state of the viscera. [illegible] present themselves in the case of insurance proposals, but radioscopic examination of the contents of the thorax is proving itself every day to be as useful as percussion and auscultation. These two latter methods only supply information as to the state of the more superficial structures, whereas radiography shows what is going on in the deep parts and enables the dimensions of organs to be ascertained. The Roentgen rays are a marvellous means of diagnosis, capable of rendering great services to life insurance companies. In this department of medical work the rays will find their chief application in the examination of the thorax and in the detection of otherwise unrecognisable disorders of the organs of respiration and circulation. Radioscopic examination of the thorax is indicated when pulmonary tuberculosis, cardiac hypertrophy, or aortic aneurysm is suspected. Various speakers discussed the subject and the opinions expressed by M. Béclère were generally accepted.

Respiratory Insufficience in Pulmonary Tuberculosis.

At the meeting of the Academy of Medicine held on June 2nd M. Mendel gave an account of an investigation of the respiration in tuberculous patients which he had made by means of the pneumograph. He had found that when a solution consisting of 5 per cent. of eucalyptol dissolved in olive oil was introduced into the air passages the effect in favourable cases of tuberculosis was the immediate production of a thoracic expansion which was observable for several hours; in the event of this result not occurring the prognosis was serious. When tracheal injections of oil containing eucalyptol were given daily for some weeks this expansion became permanent and the patient's manner of breathing might undergo considerable modification. Simultaneously [illegible]ral state improved, his [illegible] strength and weight. [illegible]culous cases appeared, [illegible]acterial infection from which they suffered and the degree of which was variable, but also to the impairment of their respiratory functions—an impairment which might be accounted for by the pulmonary lesions and the consequent encroachment on the respiratory area.

Compulsory Vaccination for Tunisian Immigrants.

An official note which has been the subject of lively comment among the Italian colony in Tunisia has just been put forth by the Government of that protectorate. The note decrees that henceforward immigrants upon disembarking at Tunisian ports will have to be medically examined and if it be considered necessary will have to be vaccinated. First- and second-class passengers will not be held to be immigrants. Moreover, a fee of 50 centimes will be charged for each vaccination. Entrance to the country can be refused to any immigrant who declines to submit himself or his children to medical inspection or vaccination.

Tænia Solium as a Detective.

It could hardly be imagined that tænia solium would aid in the discovery of a crime but an instance has occurred in the department of Eure. A convict in prison suffered from tænia for which he was treated by the medical officer. Some little time afterwards the convict, whose sentence had expired, was set at liberty, and within a few days a house in the neighbourhood was broken into. On the police examining the scene they found some excrement deposited in the middle of the room, in accordance with a gross jest which is common among some of the criminal classes. In the motion were several joints of a tænia and the examining magistrate set on foot inquiries among recently released prisoners. The man above referred to was promptly re-arrested and he, though much surprised, confessed to the crime at once.

June 9th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Care of Mentally Deficient Children.

THE Swiss Society for the Care of Mentally Deficient Children held its fourth annual meeting at Lucerne on May 11th and 12th. This society, which is doing excellent and very necessary work, finds support among all classes of society. The meetings were attended by an average of 220 ladies and gentlemen, including medical practitioners, clergymen, teachers, and representatives of various cantons of Switzerland. Most of the cantons, it may be remarked, have made joint arrangements to promote the aims of the society. Mr. Auer, the president, read a report on the progress of the work. At the beginning of the year 1901 there were in Switzerland 18 institutions accommodating 748 mentally deficient children (idiots). At the present time 868 are provided for in Switzerland and 91 have been placed in suitable establishments in Germany. Four new establishments with accommodation for 54 pupils have been opened and a new establishment for mentally deficient deaf-mutes has been opened at Turbental. According to the statistics read the number of special school classes for pupils who cannot well attend the ordinary classes in the State schools has greatly increased. In 18 Swiss towns there are now 53 such classes with 1096 pupils. Dr. Ulrich, medical superintendent of the Swiss epileptic home in Zürich, delivered an address on the Origin and Prevention of Mental Deficiency. The public, he said, were in need of instruction as to the various reasons of mental deficiency and the importance of hereditary influences. Measures ought to be adopted for the reduction of alcoholism, syphilis, tuberculosis, and cretinism, and provision must be made for the relief of the poor. Dr. Schenker of Aarau strongly advocated legal interference with regard to marriage in the case of the mentally deficient.

Swiss Society for School Hygiene.

This society, which now has 600 members, held its fourth annual meeting, which was well attended, at Schaffhausen on May 16th and 17th. Mr. Paul Lincke described a variety of practical details connected with school baths. All the newly built schools in Switzerland have now a portion of the premises appropriated for purposes of baths. Each class bathes about once a fortnight, summer and winter. The bathroom should be on the ground floor and should have from 16 to 24 baths placed at a distance of about one and a half yards from each other, so that a class of 60 children can bathe in an hour. Dr. Ost, school medical officer at Berne, spoke on the hygienic side of the question. These baths, he said, soap being used and a warm bath being followed by a cooler one, according to medical regulations, serve to take the place of hygienic methods often neglected at home. Proper excretion and secretion are thereby insured and cleanliness is encouraged. Such baths, which of course are not obligatory, should be universally introduced, only sick children and those who are suffering from skin diseases being excluded. They are also advantageous from an educational point of view, as the parents learn to take an interest in the proper hygienic treatment of the skin. Dr. Laubi of Zürich described his examinations of school children with regard to their auditory functions. He recommended that all children on entering school at the age of six years should be examined by a general practitioner or an aural surgeon, and should be re-examined in the event of them suffering from any infective disease. A second examination before leaving school, at the age of 14 years, was also desirable, as important advice might be given with regard to the choice of an occupation. Children whose hearing was very bad and who were incurable should be referred to institutions or private tuition; others should be placed temporarily in asylums for the deaf and dumb, or at school should sit in the front seats. Children with aural discharge (otitis media) should only be allowed to go to school if under proper medical care and if their ears were properly bandaged to avoid the spread of infection. Children with adenoids should be put under the supervision of the medical officer. Dr. Keller of Winterthur afterwards spoke at some length about overwork in the higher school classes in which the pupils were from 12 to 16 years of age and he pleaded for a reduction of school work in the interest of health.

Tuberculosis of the Kidney.

Dr. F. Suter of Basle has published an account of 42 cases of tuberculosis of the kidney, with special reference to the diagnosis and surgical treatment of this condition. The cases were all treated in the private clinique of Professor Burckhardt. Heiberg found by post-mortem examination that tuberculosis of one kidney occurred in 7 out of 15 cases of urogenital tuberculosis and in 17 out of 30 cases of metastatic tuberculous disease of the kidney. This is also proved by necropsies of cases which succumb after operation and clinically by the after-results of nephrectomy performed to remove one tuberculous kidney. As regards diagnosis the microscopic and chemical examination of the urine reveals nothing positive, whereas the bacteriological evidence is conclusive. In 40 out of 42 cases of tuberculous kidney no bacterial growth was obtained on culture media on which the tubercle bacillus does not develop; in the other two cases there was a growth of staphylococcus and bacterium coli which had no doubt been introduced by local instrumental interference. Appropriate culture methods revealed the existence of the tubercle bacillus in each one of the 42 cases. This is especially important, as the diagnosis may otherwise be very difficult. Such symptoms as a distinct tumour or pain on pressure being often doubtful cystoscopy is always necessary to determine which kidney is affected, the operation being contra-indicated if the other kidney is not proved to be healthy. Sometimes further investigation by experimental glycosuria, by administration of methylene blue, and by the determination of the urea derived from each ureter is necessary, or it may be desirable to determine the freezing-point of the urine excreted by each kidney (Korányi). If no operation is performed the disease will prove fatal sooner or later. Dr. Suter has published an account of 14 nephrectomies with two deaths. In the fatal cases the other kidney proved to be healthy. The 12 patients either recovered completely or their condition was greatly improved for years. Küster reports on 300 cases with a mortality of 28 per cent. Israel in Berlin has had 28·5 per cent. mortality.

NEW YORK.

(FROM OUR OWN CORRESPONDENTS.)

Adoption of a New Code of Medical Ethics in the United States.

PERHAPS the most important business transacted at the recent meeting of the American Medical Association, held in New Orleans, was the adoption of a new code of medical ethics. Dr. Harris, who read the proposed enunciation of principles of ethics, before doing so read the following special report in explanation of the action of the general committee on code.

> To the President and Members of the House of Delegates.
>
> Your committee has given extended and careful thought to the proposed revision of the code of medical ethics referred to it for consideration. As you will note on caption of report, the word "code" has been eliminated and the expression "the principles of medical ethics of the American Medical Association" adopted as adequately descriptive. In reference to this change it is proper to say that such action on its part is based on the idea that the American Medical Association may be conceived to occupy some such relation to the constituent State associations as the United States through its constitution holds to the several States. The committee for this reason regards it as wiser to formulate the principles of medical ethics without definite reference to code or penalties, thus leaving the respective States, &c., to form such code and establish such penalties as they may regard to be fitting and proper for regulating the professional conduct of their members, provided, of course, that in so doing there be no infringement of the established ethical principles of the association. The committee regards as wise and well intended to facilitate the business of the parent organisation and promote its harmony, this course, which leaves to the State association large discretional powers concerning membership and other admittedly State affairs.

The report, which is voluminous, contains three chapters and 53 sections. It would seem to cover the whole ground of professional ethics. Perhaps the most far-reaching and radical change in the code is that embodied in Section I., Chapter 2, which reads:—

> Everyone on entering the profession and thereby becoming entitled to full professional fellowship incurs an obligation to uphold its dignity and honour, to exalt its standing, and to extend the bounds of its usefulness. It is inconsistent with the principles of medical science and it is incompatible with honourable standing in the profession for physicians to designate their practice as based upon an exclusive dogma or a sectarian system of medicine.

Utilising Refuse from a Consumption Sanatorium.

The Third Appellate Division of the Supreme Court of New York had under consideration a case of conviction for disobedience of a lawful order of a board of health. It held that unless the order disobeyed was one lawfully made by the board of health the accused had been guilty of no crime. The order was one forbidding him from drawing into the corporate limits of the village any more refuse from the table and kitchen of a sanatorium for consumptives which he had been collecting for food for his chickens and hogs. There was no proof that this refuse from the sanatorium for consumptives was any more dangerous to the community than the refuse from any hotel and the court could not assume such to be the case in sustaining this conviction. Had the board of health, then, the right to forbid a person from bringing into the village refuse from any hotel or other public house, the court asked. Under the evidence in this case, it said, such refuse while it was fresh was wholesome food for hogs and fowls. The menace to the public health lay in permitting it to remain until it decayed and threw off a stench which was prejudicial to the comfort of the community if not to its health. As long, therefore, as the mere bringing into the community fresh refuse from a public place had in it no element of threatened danger to the comfort or health of this community the court was unable to see by what authority the board of health was permitted to prohibit the same. For this reason, it was added, the commission of a crime had not been proved and the judgment of conviction must be reversed.

The Sanitation of Cuba.

In a recent issue of the *New York Sun* is a long article on "The Sanitation of Cuba." This article would appear to minimise somewhat the importance of the work done by Americans in cleaning up the towns of Cuba. A part of the article in question runs as follows: "In view of all that has been said of the sanitary work of the United States in Cuba there are certain facts which stand in glaring prominence before the thoughtful investigator. For instance, virtually all of the work done has been purely superficial. With any suspension of broom-and-shovel energy every city in the island, with the possible exception of Santiago, which got a considerable amount of permanent paving, would speedily revert to its former condition under the Spanish rule. Little or none of our work has been either radical or lasting. A second point appears in the fact that to American authority is due the direct prevention of more radical measures. The Foraker law, most commendable in its general purpose and operation, prevented the granting of any concessions or franchises for public work. The sewering and paving of the city were definitely obstructed and delayed by American officials." The article goes on to say that Cuba is to-day little improved in her real sanitation beyond her condition in January, 1899. This account would seem to be on the face of it and judging from results decidedly prejudiced. The fact remains that in all the towns of Cuba the death-rate has been decreased and yellow fever apparently abolished. Surgeon-General Wyman of the Public Health and Marine Hospital Service, declares that Havana can no longer be regarded as an "endemic centre" of yellow fever, for under American rule followed by the new insular government Havana has become one of the most healthy cities of the world. In his opinion the time has passed when it was necessary to disinfect every ship that arrived at a southern port from Cuba. The Louisiana board of health, however, insists on the disinfection of vessels arriving at ports in that State from Havana and other Cuban ports and the authorities in Alabama have taken a similar course.

May 29th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Infectious Disease in Victoria.

TYPHOID fever is unusually prevalent just now in Victoria. So also is scarlet fever. An epidemic, of local origin, from water pollution has occurred at a camp of workmen employed on irrigation works at Waranga. There are about 500 people living in the camp and 45 have been attacked with typhoid fever, two fatally. Dr. D. A. Gresswell, chairman of the Board of Health, inspected the camp and found that the water-supply was seriously polluted. In the metropolis all cases of infectious disease are taken to the Melbourne Hospital which has not nearly sufficient accommodation for them. The Queen's Memorial Hospital for Infectious Disease still remains unopen but there is some prospect of a satisfactory arrangement being come to. The committee of the

Melbourne Hospital, and also representatives of the municipalities, interviewed the Minister of Health and explained the position, with the result that the Minister promised to recommend to the Cabinet that the Government should pay half the cost of maintenance. For the fortnight ending April 11th 206 cases of scarlet fever were reported, whereas for the corresponding period last year 17 cases occurred.

The Use of Preservatives in Food in New South Wales.

A recent regulation of the Board of Health of New South Wales sets out that boric acid should only be used in the manufacture of concentrated milk, among other things, in the proportion of $\frac{1}{1000}$th of a grain *per pint* or *per pound*. This means that practically no preservative at all should be used, for the quantity set out would not have the slightest effect on the milk. The Board of Health, along with other sanitary authorities, believes that none is required, but according to the wording of the statute a certain amount must be specified. That is why the absurdly small proportion of $\frac{1}{1000}$th of a grain is fixed upon. On the other hand, it has been represented to the treasurer that unless some modification is made in this regulation it will be impossible to carry on the industry. The State treasurer held a conference with the board on April 14th with the view of ascertaining whether a compromise could not be effected which, while safeguarding the public interest, would enable the manufacturers to proceed with their business. However, after consultation it was decided to adhere to the board's regulation.

An Alleged Cancer Cure.

A deputation, styling itself the Victorian Cancer Research Association, waited on the chairman of the Board of Health to submit three alternative propositions. The first was that a departmental scientific inquiry should be made as to the effectiveness of an alleged cure for cancer practised by a layman calling himself "Professor" Davis; secondly, that a medical man should be selected to work with the "professor" who should be immune if a patient should die under treatment; and, thirdly, that the Government should purchase the specific if cures were effected. The deputation was most enthusiastic in its advocacy of the new treatment, stating that the "professor" had succeeded where medical men had failed. It professed to have a horror of the knife of the surgeon and to have a profound belief in the remedy applied. Dr. Gresswell, in reply, pointed out that in four out of five cases in which patients had died under the "professor's" treatment a considerable quantity of arsenic had been found in the bodies. Further, he said, the "professor" did not claim to cure internal cancer, only superficial growths, and these were cured by medical men, in some cases without resort to the knife. He had no doubt that the ingredients of their lotions were similar to those used by the "professor," only that they were applied in different quantities. As the "professor" would not disclose his secret he saw no use for a Government inquiry. As to the second proposition he had no power; it involved an alteration of the present law of the land. He concluded the interview by stating that the deputation had not shown him how he could help it at all in the matter.

Hospital News.

The report presented to the annual meeting of the supporters of the Prince Alfred Hospital, Sydney, stated that the hospital had now been opened for 20 years and would attain its majority on Sept. 25th next. As it had grown in years, so it had grown in usefulness, and during the past year showed an advance in every respect. The number of in-patients reached its high-water mark in 1901 and last year the number was practically maintained, while the serious operations numbered almost 200 more than in the previous year, the total having reached 2077. The congested state of the wards, to which reference had been made year after year, had continued, so that with 236 beds available there were 230 always occupied on the average, which meant that on some days there were a great many more than this number. As a matter of fact, as in 1901, no less than 252 patients had been in residence on certain days. This meant that shakedowns and other temporary accommodation had to be resorted to, but this state of things would be remedied when the new pavilions were opened.—The governors of the Melbourne Hospital decided last year that the honorary staff should be increased by the appointment of a fifth indoor physician and a fifth indoor surgeon. The committee has given effect to this decision by appointing the senior physician to out-patients, Dr. J. E. Nihill, and the senior surgeon to out-patients, Mr. G. A. Syme, as physician and surgeon to in patients respectively; to the positions on the out-patient staff thus made vacant the committee has appointed, as physician, Dr. J. F. Wilkinson and as surgeon, Dr. J. Gordon.

A Medical Man committed for Perjury.

At the Fitzroy (Victoria) Court Dr. Abraham Wheeler was committed for trial on a charge of perjury. On March 25th Dr. Wheeler was fined for using insulting language and on that occasion swore that he did not use the language attributed to him. In so swearing he was stated to have committed perjury. The evidence was conflicting, but the police magistrate considered a *primâ-facie* case had been made out and he would leave the matter for a jury to decide.

Obituary.

The death is announced of Dr. Richard Ryther Steer Bowker, M.L.C., at the age of 88 years. For some time past he had been ailing and on April 3rd he passed peacefully away. Dr. Bowker was born in Lincolnshire in 1815. At the age of 16 years he was apprenticed at the Nottingham General Dispensary. After serving his time there he became a student of medicine in Scotland, afterwards in London, and finally in Paris. He commenced to practise at Bingham in Nottinghamshire at the age of 22 years, and quickly gained an extensive practice. But his health failing him he was compelled to take a long sea voyage, so he obtained an appointment as medical superintendent of an immigrant ship and ultimately settled in Newcastle, New South Wales Again his medical skill and genial disposition soon won for him a large practice and a number of friends. When he first settled in the colony he associated himself with many public movements and the services he rendered to Newcastle were recognised by his fellow townsmen who in 1856 asked him to stand for Parliament. He was elected to the Assembly in the same year, but on the dissolution of the House in 1859 did not offer himself for re-election. He removed to Sydney shortly afterwards and was in 1877 again elected as one of the free-trade representatives of Newcastle. Subsequently he was appointed to the Legislative Council and although he never took a very active part in politics he was a constant attendant at the House. Although of late years Dr. Bowker, owing to his extreme age, was practically compelled to give up the practice of his profession, he was in his prime one of the most skilful surgeons in Australia and earned for himself a great reputation as an ophthalmic surgeon. In 1858 he married Lydia, the youngest daughter of Mr. Phillips of the Paterson, who died in 1878 Three daughters and five sons, all of whom are medical men, survive him.

May 4th.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—This hospital is being rebuilt and reorganised. The sum of £50,000 is urgently needed and this need will be brought before the eyes of the public by means of a captive balloon which is to float over the site. The ladies' committee which has been formed to help the hospital will meet about the end of June.

LITERARY INTELLIGENCE.—Mr. Heinemann has just ready for publication a small volume entitled "Hay Fever and its Successful Treatment." Sections are devoted to its history, causes, time of occurrence, duration, &c., and there is a discussion upon the pollen theory. The author is Mr Hollopeter, clinical professor of pediatrics in the Medico-Chirurgical College of Philadelphia and a Fellow of the American Academy of Medicine.—The following books will be published in June by Messrs. J. and A. Churchill: "The Microscopical Examination of Foods and Drugs," by Mr. H. G. Greenish, professor of pharmaceutics at the Pharmaceutical Society; "Serum-Therapy," by R. T. Hewlett, professor of general pathology and bacteriology, King's College, London; "Disinfection and Sterilisation for Nurses and Others," by Dr. F. W. Andrewes, lecturer on pathology at St. Bartholomew's Hospital; "Modern Bullet Wounds and Modern Treatment," by Major F. Smith, R.A.M.C., D.S.O.; "On Syphonage and Hydraulic Pressure in the Large Intestine," by Dr. R. W. Leftwich; "An English Handbook to the Paris Medical School," by Dr. A. A. Warden, physician to the Hertford British Hospital, Paris; the second edition of "Infant Feeding," by Dr. E. Cautley; the fourth edition of "Lectures on Medicine to Nurses," by Dr. H. E. Cuff; and the fifth edition of "Uric Acid," by Dr. A. Haig.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

SATURDAY, MAY 30TH.

THE Council resumed its proceedings, Sir WILLIAM TURNER, the President, being in the chair.

Final Examinations.

Mr. BRYANT moved the adoption of the reports from the Examination Committee on the inspection of the final examinations of the Universities of Victoria, Durham, and Cambridge which were received and entered on the minutes yesterday.

After a brief discussion on minor points of detail the motion was adopted.

The Society of Apothecaries of London.

Mr. BRYANT presented a report from the Examination Committee on the inspection of the primary examination in chemistry, physics, and biology of the Society of Apothecaries of London. The committee stated:

> This examination is in many respects similar to the examination held by the English Conjoint Board in the same subjects. The latter body does not accept the Apothecaries' examination *in lieu of its own*. The Apothecaries' Society does accept the examination of the Conjoint Board. Certain points of difference between the two are indicated in the report of the visitors.
>
> *Biology.*—There is no paper and no practical test, the examination, as at the Conjoint Board, being of a purely oral character. Conducted on the same lines as the last-mentioned examination and, as far as the visitors could judge from the two candidates who alone presented themselves for it, the examination is of a very similar standard. The visitors consider that the examination would be much improved by the addition of a paper and practical work. This committee agrees with the visitors in the recommendation to add a written and practical part to the examination in biology.
>
> *Physics.*—The paper work in connexion with this subject consists of two questions on the same paper as that dealing with chemistry; nust be answered. In this respect the examina- the Conjoint Board, but in addition there is *a feature which is lacking in the other case.* The oral examination forms a part of that dealing with chemistry and the report shows that it is of a practical character. The practice of the Society in requiring an oral examination is commended by the visitors. They suggest that three questions should be set in the physics section of the paper, that the candidates should be required to answer at least two of these, and that no candidate should be allowed to pass in physics should he fail to secure adequate marks in that subject, even if he should obtain 50 per cent. on the entire paper. With these recommendations the committee concurs and in addition desires that the subject of physics should be dealt with in a separate paper.
>
> *Chemistry.*—This examination closely resembles that of the Conjoint Board, being, according to the opinion of the visitors, stronger in one respect and weaker in another. It is stronger in that every candidate is required to submit to an oral examination, a test which is only demanded from those on the line by the regulations of the Conjoint Board. On the other hand, it is reported that the practical examination does not include the preparation and exhibition of specimens of compounds. The visitors regard this as the most valuable part of the practical work demanded by the Conjoint Board. With respect to the practical examination the visitors report that the standard is too low and that "it is of a kind that is of extremely little value, either as a training for the student's intellectual powers, or as a preliminary to the study of physiology, or as giving him something that would be useful to him in his future career." From what has been said it will be gathered that the visitors do not regard this examination as a sufficient test nd of their first year in the subjects with ew the committee concurs. The court of the Council for its report, and promises that it shall have careful consideration.
>
> The committee trusts that the deficiences to which attention has now for the first time been called will not merely be noted by the court but that they will be rectified and thus bring the examination up to a sufficient standard. The committee is in agreement with the visitors "that the average training of candidates is insufficient for men who are commencing medical studies."

On the motion of Mr. BRYANT the report was received and entered on the minutes and its consideration was postponed till the special meeting on July 15th.

The Finances of the Council.

Sir VICTOR HORSLEY presented the following report from the Financial Relations Committee of which the President is chairman:—

> It was resolved that the committee approve, and recommend the General Council to adopt, the President's memorandum on the present inadequacy of the income of the Council as the basis of an appeal to the proper authorities. The committee proceeded to consider a summary of suggestions received from members and the General Registrar as to economies that might be practised by the Council. The committee cannot recommend the General Council to adopt any of the modifications suggested for the conduct of penal business. As to the days of the session and their duration, the committee recommend that one hour be added to the daily session of the Council and that the hours of sitting be from 1.30 till 6.30, except on Saturday. The committee also recommend that on the first day of each session of the Council standing committees should meet at 12 o'clock noon. Of the suggestions made as to the fees of members, the committee approve the following:—1. That members should be paid for their services, and that the fee should continue to be £5 5*s.*, as at present. 2. That the travelling expenses of members by rail and steamer should, in accordance with the approved practice in the public service, be limited to the actual outlay, together with some fixed allowance, say one guinea, for incidental expenses to and from London. The committee to amendments in the rules of debate. *Council* to appoint a small committee site of the Council office, to consult an expert valuer as to the value of the Council's property in Oxford street and Hanover-square as a whole or in parts, and report to the Council. With re ee recommend:—1. That the issue of the minutes should be discontinued. rly volume of minutes to be ordered should be 200 instead of 300. 3. That as soon as possible the printing of the Medical Register should be transferred to the Council's own printer. 4. That 1000 copies should be ordered each year instead of 1350 as at present. 5. for leave to raise the committee postponed ment Bill, which was included in the reference, pending the result of an appeal *to the Government for a grant towards meeting* the deficiency in the Council's income.

Sir VICTOR HORSLEY moved the adoption of the recommendation.

> That the Council adopt the President's memorandum on the present inadequacy of the income of the Council as the basis of an appeal to the proper authorities.

Dr. WINDLE, in seconding the motion, said that the President's memorandum contained a reference to the Incorporated Law Society which received a grant from the Treasury and he (Dr. Windle) would suggest that a reference should also be introduced *in relation to another body* which had powers almost analogous to the General Medical Council—namely, the Teachers' Registration Council which was formed under the powers of the Education Act of 1899. The latter body was not responsible to the Privy Council like the General Medical Council, but was responsible to the Education Department The income of the Teachers' Registration Council would never reach more than £800 or £1000 per annum and the expenses could hardly be less than £2000 a year. When the Order in Council was laid on the table of the House of Commons a question was raised by a Member as to the financial position of the body and it was pointed out that it was impossible that it could be self-supporting. The reply of Sir John Gorst was to the effect that in that case the Education Department would have to make good the deficit Dr. Windle would therefore suggest that the Teachers' Registration Council would be a very proper parallel to introduce into the President's memorandum.

The PRESIDENT said that he would consider the matter.

Dr. NORMAN MOORE said that he could not agree to the committee's recommendation. The Council had no right whatever to ask for money from any public body. The present session showed that they did not manage their business affairs in a satisfactory way. The cases that were brought before them by the Penal Cases Committee were drawn up in a way which led to an enormous waste of time. Speaking generally, he was entirely opposed to the principle of going to the Government and asking for public money. If the Council passed a resolution that the fees *for* registration ought to be increased they would be trying to get money from their own profession. He should disapprove of that, but he should disapprove of it much less than applying to the Government for a grant. He thought that the Council had in a variety of ways endeavoured to grasp powers which were beyond it, and had given an amount of time to various subjects which it would have been much better if it had left alone. Therefore, he was opposed to making any request fo a grant of public money.

Mr. BROWN did not think the time had arrived when a appeal should be made for a grant *from* Parliament. When he considered that the Council had invested in its building something like £40,000 and had other investments he could not see that its financial state was such as to necessitate an appeal to Government for money. Before it applied for public money, or for powers to exact more money from the medical profession, it should spend what it had He believed that much of the time of the Council might be saved in connexion with the work of the Penal Case Committee.

Sir VICTOR HORSLEY as a member of the Penal Case Committee objected on a point of order to Mr. Brown's and

Dr. Norman Moore's remarks. If the administration of the Penal Cases Committee was to be challenged it ought to be done on a direct issue. It was not fair to introduce the matter into a debate on the finances of the Council.

The PRESIDENT agreed with Sir Victor Horsley in his objection.

Dr. NORMAN MOORE said he was not attributing any errors to Sir Victor Horsley or anyone else. It was the methods of the Penal Cases Committee, not the conduct of individual members, that he objected to. He had criticised the general way in which the business was done.

Mr. BROWN said he was endeavouring to show that if the penal cases, instead of being referred to the Penal Cases Committee, were referred to the branch councils the expense would be infinitely less than it was under the present procedure.

The PRESIDENT pointed out to Mr. Brown that he was now raising a wider question than that immediately before the Council.

Mr. BROWN concluded by saying that he would vote against the motion because the Council had not yet exhausted its resources.

Sir CHRISTOPHER NIXON said that the work of the Council had very considerably increased in recent years and additional duties had been imposed upon it. If it was in the interests of the public at large that it exercised these duties, and especially in connexion with its penal jurisdiction, he did not see why the State should not pay the expenses that were incurred by the Council in carrying out that work. Why should the State not contribute to the legitimate expenses that were incurred by the Council in protecting the interests of the public? He thought that the Council had much more reason to apply to the State than to ask the medical profession to penalise itself to carry out work which was done in the interests of the State and the public at large. If the State refused to grant them any money the only alternative they had was to impose a penalty on the profession.

Dr. FINLAY thought that the strong justification for applying to the Treasury was the fact that so much of the work of the Council was in the interests of the public and not in the interests of the medical profession *per se*.

Dr. LITTLE supported the motion.

Sir JOHN TUKE pointed out that if a grant to the Council was placed on the Estimates it would be subject to the review and criticism of the House of Commons and to that extent the Council would lose its independence.

Dr. BRUCE said that the only criticism he could offer in connexion with the Penal Cases Committee was that perhaps it did not take as much legal advice as it might do

The PRESIDENT did not think that the position of the Penal Cases Committee was fully understood. That committee was in the position of a grand jury. There were certain *primâ facie* facts brought before it and all the committee did was to say whether there was a *primâ facie* case. All the cases had to be thrashed out in the Council and there was a quantity of evidence brought before the Council which the committee could not have before it. The committee exercised its judgment in the best way it could on the facts presented to it in the preliminary stage of the inquiry.

Mr. BRYANT: We have both our legal advisers with us in every case.

Dr. PYE-SMITH said that in dealing with money as trustees for other people there was one vice to be avoided—namely, profligate expenditure; but there was also another vice—namely, penuriousness and niggardliness, and they had to hit the golden mean. The golden mean was proverbially difficult to traverse. He ventured to think, if this motion was passed, that when they went to the Government and asked for help they would be met by this question: "How have you dealt with your money already?" and he doubted whether they could offer a complete justification for their expenditure. Their first business was to see what they could do with the money they had, and when, after making all retrenchments compatible with efficiency, they found that their funds were not sufficient, then they might justly go to the Government for help. He thought if they were asked they should have to confess that they did spend too much time in unprofitable wrangling and too much time in long meetings. And now they were threatened with more frequent meetings—more than two sessions in the year—and they were allowing the number of members of the Council and the number of their sittings to increase almost every year without taking any measures to prevent it. Before giving up their independence by applying for public money he thought they should use every means in their power to see what they could do to limit their expenditure. He would remind the Council of the blessed words, "Peace, retrenchment, and reform."

Dr. MACKAY said that Dr. Pye-Smith talked about the Council giving up its independence by applying for public money. He believed that no member of the Council would care to sacrifice his independence in that way. But he would point out in this connexion that the universities of Scotland, though they received a grant from the Government, were absolutely free from any interference or control except in so far as Parliament could by a special Act interfere with every institution in the country. If the Council got a grant from the Treasury—and he thought it should—it would not be accompanied by any condition which would hamper the work of the Council.

The PRESIDENT said that if the Council got money from the Treasury with the sanction of Parliament and that money was not on the Consolidated Fund it would be subject to review year by year when the vote was taken in the House of Commons. The moment the House had a vote submitted to it for consideration any Member could criticise and discuss it.

Dr. MCVAIL said he was a little confused by Dr. Pye-Smith's speech. He had now applied to the Council the term "profligate."

Dr. PYE-SMITH: No; I did not apply the term "profligate" to any member of the Council. What I said was that the Council should avoid the vice of "profligate expenditure."

Dr. MCVAIL said that if the Council was spending too much money surely the very best thing to do was to bring its profligacy under the notice of Parliament annually. He would welcome Parliament having annually the power of reviewing the work of the General Medical Council. He thought its action ought to be open to the inspection of Parliament. The Council was still in the possession of considerable funds. Was it a good time to apply to the Government for more money when it was in possession of a considerable surplus? Was it certain that in coming years the Council would have as much penal work to do? "Covering" cases had practically disappeared; the men now entering the medical profession were more highly qualified; and he anticipated in future years a considerable diminution in the number of penal cases that came before the Council. He was not at all in despair that the Council would be able in the future to save money, because he thought it was almost certain that its penal work would decline. He should therefore feel disposed to let this matter rest for the next two or three years. He did not think that the Government was in the least degree likely to listen to them if they made an appeal for more money at the present time.

Sir VICTOR HORSLEY, in replying to the discussion, said he hoped to bring up the whole question of penal work in a future session. Dr. Pye-Smith reminded the Council of the blessed words, "Peace, retrenchment, and reform," but there was another blessed word—"efficiency." It was just that efficiency which the Council lacked at the present moment because they were spending their accumulated funds. They had spent £10,000 in the last seven years. The President's memorandum would for the first time draw the attention of [illegible] of the Council. In order to [illegible]ney.

[illegible]ORSLEY'S motion was carried by 21 to 3.

The PRESIDENT: It is quite evident that the memorandum will have to have an alteration made in it in the direction indicated by Dr. Windle. When shall I do it?

Sir VICTOR HORSLEY: That must be left to your convenience. I move, Sir, recommendation No. 2, viz.:—

[illegible] following resolutions be adopted and :—
[illegible] day except on Saturday at 1.30 P.M.
[illegible]

(e) (1) That the [illegible] be discontinued (f) (2) That in future 250 copies only of the yearly volume of minutes be printed. (g) That as soon as possible the printing of the Medical Register be transferred to the Council's own printer. (h) That 1000 copies only of the Medical Register be ordered each year. (i) That application be made to the Treasury for leave to raise the price of publication of the Medical Register to 10s. 6d.

Sir JOHN TUKE seconded the motion.

Sir WILLIAM THOMSON opposed the extension of the daily sittings as proposed in (a). Even now when five o'clock was reached he felt that they did not care very much for the business. He did not think the work could be better done by adding to the hours for doing it.

Mr. JACKSON quite agreed with Sir William Thomson. He thought before he came to the Council that it did not work hard, but since he had been a member he had found out differently.

Mr. BROWN moved that the Council should not sit beyond six o'clock.

Dr. MACALISTER seconded this proposal. At present six o'clock meant seven to the Business Committee.

On a vote Mr. Brown's proposal was defeated by 13 votes to 11, and the Financial Relations Committee's recommendation (a) was rejected by 16 votes to 12. The other recommendations except (d) were carried; (d) was taken *in camerâ* and no announcement was made of the result of the consideration.

On the motion of Dr. MACKAY and supported on a vote by 21 members it was agreed—

That the fee for re-registration be raised to £1, that the fee for the registration of each additional qualification be raised to £1, and that the fee for public health registration remain as at present.

Finally, the Executive Committee was requested to take steps for making changes in the Standing Orders where necessary to bring them into conformity with the several motions passed.

Finance Committee's Report for 1902.

Mr. BRYANT moved that the following report, to which were appended the several carefully compiled tabulated statements referred to in it, should be received and entered on the minutes:—

The Finance Committee report that the income of the General and Branch Councils for the year ending Dec. 31st, 1902, was £8591 8*s.* 7*d.*; the expenditure for the same period was £9924 6*s.* 8*d.*, consequently there is a deficit on the year's working of £1332 18*s.* 1*d.*

From Table A it will be seen that the receipts from fees show a decrease of £349 8*s.*, the English Branch having received £49 5*s.* less, the Scottish Branch £346 6*s.* less, and the Irish Branch £45 17*s.* 6*d.* more than in the previous year.

A statement of the expenditure of the General Council compared with former years will be found in Table B. The following items call for explanation. (*a*) An increase of £793 16*s.* in General Council fees, mainly due to the special session in February which cost upwards of £650, though against this may be set the decrease of £80 in the cost of the Executive Committee meetings due to one payment for travelling expenses covering both meetings. (*b*) An increase of £115 1*s.* 6*d.* in law expenses; the case of W. A. Jones alone cost over £100. (*c*) An increase of £143 7*s.* 3*d.* in the cost of inspection of examinations due to the larger numbers of bodies under review. (*d*) The sinking fund and grant to the Irish Branch are dealt with below.

It will be noticed that wherever possible expenses have been kept down and that there has been a considerable economy in such items as printing and miscellaneous expenses. Table C shows comparatively the income and expenditure of the Branch Councils for the past three years: the English Branch had again to meet the expenses of a contested election. From Table D it will be found that the excess of expenditure over income is about £170 less than the average for the past seven years. The percentage rate is 94·48, which is 1·66 above the average. Table E shows that the assets of the branches have decreased by the amount of the year's deficit. The Pharmacopœia accounts, as will be seen from Table F, show a profit of £549 18*s.* 10*d.*, which is mainly due to the sale of the Government of India Edition of the Indian and Colonial Addendum. Of this sum £500 has been placed on deposit with the National Provincial Bank of England, being repayable at call and bearing interest at current rates, which roughly may be taken to be 1½ per cent. below Bank rate. The Bank of England allows no interest on deposits.

Sinking fund.—In accordance with the resolution of the Council notice was given to surrender the policy, the value of which proved to be £408 16*s.* The amount paid in premiums was £646 17*s.* 6*d.*, so that practically one year's premium was lost. The value of the policy has been credited to the General Council's receipts and it should be noted that the deficiency on the year's working is thereby decreased from what it would otherwise have been.

Irish Branch.—It was not thought necessary last year to give a grant to the funds of the branch and the result was that at the end of the year the net balance in hand was £78. It may be assumed that the receipts this year will be approximately the same as last—say £800—and it is expected that the expenses will be £100 less owing to the change in office arrangements; on this basis there will be a deficiency at the end of the year of about £250, and the committee therefore recommend that a grant of £300 be made towards the funds of the branch.

Dental Finance.—Table G shows that there was a surplus of income over expenditure of £249 12*s.* 10*d.* A further sum of £600 has been advanced to the English branch.

On the motion of Mr. BRYANT, seconded by Dr. PYE-SMITH, it was agreed:—

That a grant of £300 be made towards the expenses of the Irish Branch Council for the current year.

Canadian Practitioners.

Mr. TOMES asked the President, in reference to the suggestion for an amendment of Part II. of the Medical Act, 1886, contained in his address to the Council, whether he could state that that suggestion was likely to be favourably regarded by the Government of the Dominion of Canada or by the medical authorities who had given their adhesion and support to the Canada Medical Act, 1902.

The PRESIDENT: I think the best way to reply to this question is to give a little narrative of the circumstances which led me to make a reference to it in my opening address. It was largely due to the interest one takes in endeavouring to put Canadian medical practitioners on a proper footing as regards our British Medical Register. At last November meeting I dwelt for some time on the Canadian Act so as to show what that Act was to do and to show that if Canada carried out the provisions of that Act there should be reciprocity. But at the end of April or beginning of May Sir John Tuke put into my hands a letter received by him from Dr. Roddick, a member of the Canadian Legislature—the member who carried through this Act—which contained these words:—

You are probably aware that before the Canada Medical Act, 1902, could come into operation it was necessary that all the provinces should consent to the measure. I regret to say that within the last few days the legislature of the province of Quebec rejected the measure by a large majority. This, of course, puts a stop to my work for the present, and unless I succeed in getting an amendment through the Dominion House, of which I am a member, during the present session it is possible that the Act could not come into *operation for many years. I can, therefore, no longer* advise those interested to interfere with General Laurie in his laudable endeavour to assist Colonial graduates to serve the empire in the naval and military and civil services of the Crown.

In view of the fact that Quebec would not give up its independence and come under the general scheme, which made it quite clear that we could not look for several years for Canada being brought into line with, say, Australia, I called attention to the matter. You will observe that General Laurie's Bill proposed the overcoming of the difficulty—that is to say, that the Privy Council might put certain provinces on the basis of reciprocity. That was the matter that went through my mind at the moment and that is the reason why I made the suggestion. The whole question is under the consideration of the home authorities and something must be done because it is manifestly in my judgment most unjust that whilst practitioners coming from Australia can enter easily into the service of the Crown practitioners coming from Canada cannot. To come to the question—I am unable to say whether the suggestion I have made is likely to be favourably regarded.

Sir JOHN TUKE: General Laurie has introduced a revised Bill in which the federation of Australia is taken into account.

The PRESIDENT: Yes; prior to two years ago Australia was treated as three different States and reciprocity was given to each of these three. Now that these States are federated into a great Commonwealth it is a question how far we can recognise reciprocity as between the home country and them. They are Victoria, New South Wales, and South Australia. The question of Canada and Australia must be considered so as to place the subject on a general footing.

Mr. TOMES said that he also had received a letter from Dr. Roddick in which the writer of it stated that he had knowledge of General Laurie's Bills and that letter conveyed rather a different impression from that received by Sir John Tuke. Dr. Roddick pointed out that he would not hinder in the slightest the adoption of General Laurie's scheme, but he should prefer that his own Bill should become operative. He believed also that the Dominion Parliament would assent to his Bill, for five or more provinces had adopted it. All the provinces except Quebec were in favour of it. He (Mr. Tomes) concluded by moving—

That the President be requested to communicate with the proper authorities in order to ascertain whether the suggestion made in his address as to reciprocity for Canada is likely to be favourably regarded by the Government of Canada or by the medical authorities who have given their adhesion and support to the Canada Medical Act, 1902.

Sir VICTOR HORSLEY seconded this motion and the Council agreed to it.

Dental Examination and Education Committee.

On the motion of Mr. TOMES the following report was received and entered on the minutes:—

The committee met on Wednesday, May 27th, 1903.

An Act relating to the practice of dentistry, South Australia, 1902, has been referred to your committee for its information. In this Act all of the dental licences of this country, as well as that of the Dental College of Sydney, are cited as entitling to admission to the Register *and power is given to recognise* such other diplomas as the board may think fit and, subject to the fulfilment of a condition, *that of the* University of Adelaide is added to the list of recognised degrees. The report.

In 1900 an application made by the Royal College of Dental Surgeons of Ontario to the General Medical Council was considered (Minutes 1900, pp. 169, 361-67). In this application it was proposed that
ersons holding

only refer to the opinion then expressed, to which, the circumstances not having altered, they adhere.

Approval of a Teaching Institution.

The report of the Students' Registration Committee which, on Sir HUGH BEEVOR'S proposal, was received and entered on the minutes, showed that the committee had resolved

That the Polytechnic Institute, Battersea (day classes), be added to the list of recognised institutions approved by the Council.

The Battersea Polytechnic has been adopted as one of the schools for internal students of the University of London.

Officials of the Council.

Dr. MACALISTER moved:—

That the President be requested to express the thanks of the Council to Mr. N. C. King for his services in preparing an index of the Council's minutes (1886–1902).

Sir JOHN BATTY TUKE seconded the motion, which was agreed to.

The PRESIDENT had pleasure in expressing to Mr. King thanks for the work which he had done voluntarily. They were very much obliged to him for the time and labour he had devoted to it.

Dr. MACALISTER moved the re-appointment of Mr. H. E.
or the Council until the close of

express how much he owed to Mr. Allen in connexion with business. It would be impossible for a non-resident President to conduct the affairs of the General Medical Council unless he had the careful and active coöperation which Mr. Allen had invariably given,
value to any opinion that

o.

Thanks to the President.

Sir CHRISTOPHER NIXON said that he should like to have the privilege of moving a vote of thanks to the President for the way in which he had presided over their deliberations and the extremely efficient way in which he had maintained order amongst the disorderly members, including himself (Sir C. Nixon).

The PRESIDENT could not conceal from himself that the meeting had been a very trying one—he had never attended a meeting which had strained his attention so much as the present—and he thanked them very warmly, not only for this vote of thanks, but also for the consideration with which those disorderly members among whom Sir Christopher Nixon placed himself had met any suggestion made by him.

The Council rose till July 15th.

Medical News.

TRINITY COLLEGE, DUBLIN.—At examinations held at *Trinity term the following* candidates were successful:—

UNIVERSITY OF CAMBRIDGE.—The University lectureship in midwifery, now held by Dr. A. F. Stabb, will be vacant at Christmas. An appointment will be made in the Michaelmas term. Candidates are requested to apply to the Vice-Chancellor before Oct. 20th.—Mr. A. C. Seward, F.R.S., has been reappointed lecturer in botany.—The city *isolation hospitals, Bristol, have been recognised by the* University for purposes of medical study.

PRESENTATION —Mr. George A. Davies, L.S.A., J.P., who has practised in Newport (Mon.) for nearly 30 years, has been presented by his friends and patients with a silver tea kettle, a silver tea service, and a diamond ring upon his leaving Newport.

DONATIONS AND BEQUESTS.—By the will of Mr. William Highfield Jones, of Waverley House, Goldthorn-hill, Wolverhampton, £1000 are left to the Wolverhampton and Staffordshire Hospital.—The trustees of Aston Villa Football Club have presented to the General Hospital, Birmingham, a cheque for £1250, raised by subscriptions, for the endowment of a footballers' bed.

ISOLATION HOSPITAL FOR DAWLISH.—A public meeting, convened by the urban district council, was held at Dawlish on May 28th, under the presidency of Dr. Charles N. Lovely, to consider whether an isolation hospital should be provided from the rates or by voluntary subscriptions. After considerable discussion it was unanimously resolved that the council should be informed that whatever was done should be paid for out of the rates.

THE MEDICAL MAN AND THE BURGLAR.—About 4 A.M. on June 3rd the residence of Mr. W. E. Good, M.R.C.S. Eng., L.R.C.P. Edin., of High-street, Dorchester, Dorset, was entered by a burglar. After ransacking the lower parts of the house the man entered Mr. Good's bedroom and making a slight noise awoke Mr. Good who leaped out of bed and after securing the intruder opened a window and shouted for the police. A constable soon appeared and the man was taken into custody..

DINNER TO DR. G. E. HERMAN.—On June 8th Dr. Herman was entertained at dinner at the Café Royal, Regent-street, London, by his old resident accoucheurs, on the occasion of his retirement from the post of senior obstetric physician to the London Hospital. In the unavoidable absence of Mr. T. Horrocks Openshaw, C.M.G., the chair was taken by Dr. Fenton. In proposing the toast of the evening the chairman eulogised Dr. Herman's valuable work at the London Hospital during the past 27 years and dwelt upon his admirable contributions to obstetrics and gynæcology and the important services which he had rendered to his pupils by his teaching and example. The gathering was most successful, men coming from all parts of the country to show their affection and loyalty to their former chief.

ANNUAL DINNER OF THE WEST LONDON HOSPITAL.—This dinner was held at the Empire Hall of the Trocadero Restaurant, Piccadilly-circus, London, on June 8th. It forms a regular reunion of the staff of the West London Hospital, present and past, of the present and past resident staff, and of the members of the Post-Graduate College established in connexion with the institution. The chairman of the dinner, Dr. J. A. Mansell Moullin, proposed "The West London Hospital, including the Post-Graduate College, and the Past Residents," and Mr. L. A. Bidwell (the dean), in reply, said that the Post-Graduate College was established in 1895 to supply clinical instruction to medical men in practice in the country and in the colonies. There were a large number of medical officers from the navy and army constantly in attendance. Since the establishment of the college no fewer than 600 medical men had been students and since Jan. 1st as many as

166 fresh members had been enrolled. The West London Hospital was the only important general hospital in London where practice and clinical teaching were reserved for qualified men; a special building for the accommodation of post-graduates had been erected in the hospital grounds and a spacious pathological department would be provided. Sir William S. Church, Bart., K.C.B. (President of the Royal College of Physicians of London), in the course of acknowledging the toast of "The Visitors," proposed by Mr. W. Bruce Clarke, said that in listening to the speeches made that night he was struck by the great confidence everyone felt in the future of the hospital, which was perfectly justifiable because all connected with them knew that the hospitals of London with medical schools could not provide post-graduate courses. In conclusion, he warned his hearers that the hospital must not expect such a large contribution as it had received last year from King Edward's Hospital Fund because it was not reasonable to suppose that every year would yield such a "bumper" revenue as the last year had—a forecast that it is to be hoped will prove incorrect.

Parliamentary Intelligence.

HOUSE OF COMMONS.

MONDAY, JUNE 8TH.

The Infected Blankets.

SIR THOMAS DEWAR asked the President of the Local Government Board whether the hospital blankets which reached this country from South Africa as discarded War Office stores had yet been traced in the [illegible]

I sent a circular letter to about 200 sanitary authorities in England and Wales in whose districts it was reported that some of the blankets referred to had been received and advised them as to the measures which should be adopted in order to safeguard the public against any possible infection from the blankets. I have not received reports from all the authorities, but, so far as my information goes, I have every reason to be satisfied with the action taken in matter.

Sir THOMAS DEWAR asked the Secretary of State for War whether he had yet received from the General Officer Commanding in South Africa a report explaining the circumstances in which discarded hospital blankets were sold in South Africa; whether he would state the result of the inquiry, the number of blankets sold, and the amount which they realised; and, in the interest of public health, whether he would consider the expediency of issuing instructions that all stores composed wholly or in part of textile fabrics which had been used in the field, whether in hospital or otherwise, should be carefully disinfected before they passed out of the hands of the military authorities.—Mr. BRODRICK replied: The General Officer Commanding, South Africa, reports that in October last, owing to the rapid demobilisation of the troops, an enormous stock of unwashed general service blankets, returned to store by the troops on demobilisation, was stored at the Cape Town Ordnance Stores, stacked in the open under tarpaulins. Efforts were made to have these washed and properly stored, but meanwhile the stacks took fire by spontaneous combustion and endangered the entire ordnance depôt. Prompt action became imperative and the chief ordnance officer gave instructions for large numbers of those in the worst condition to be destroyed by fire and accepted tenders for the sale of 80,000, provided they were removed within three days. Those blankets were not unserviceable though they had not been washed. The amount realised by the sale was £1495. Medical officers have, under the regulations, power to destroy any articles of public property on sanitary grounds and are expressly ordered to disinfect all soiled bedding which has been in contact with the sick. I am not prepared to issue so wide an order as that suggested —that all textile fabrics which have been used in the field should be [illegible] s previously stated, the ordnance and [illegible] instructions as to the disposal of con- [illegible] I also issued special orders forbidding the sale in South Africa of any textile article which might convey infection. There appears to have been an error of judgment on the part of the responsible officer who had otherwise done excellent service. The military authorities are investigating the matter.

Sir THOMAS DEWAR asked Mr. Brodrick whether he would state the number of discarded military tents which had been sold in South Africa and the amount which they realised; whether they were disinfected and whether were they sold by tender or by public auction; and whether he would also state the number of hospital tents sold and say whether any, and if so what, steps were taken to secure their disinfection.—Mr. BRODRICK replied: About 2760 tents are known to have been sold, of which only four were hospital marquees. They were sold by auction and tender. The amount realised was £970. Under the medical regulations medical officers are authorised to destroy public property on sanitary grounds when necessary and are also in possession of stringent instructions regarding disinfection. I have no reason to suppose these instructions were disregarded.

Imported Milk.

In Committee of Supply on the vote for the Customs Department, Sir EDWARD STRACHEY raised a debate on the question of imported milk and in particular complained that the Customs Department refuses to give information as regards the names and addresses of persons in this country to whom foreign milk is consigned and by whom it is sold. Sir Edward Strachey and other Members contended that purchasers have the right to know where the milk they buy is produced. The reply made on behalf of the Government was to the effect that the Customs Department has no power to give this information and that the proper line of reform is by way of legislation.

TUESDAY, JUNE 9TH.

The Sewage of Longmoor Camp.

Mr. HEYWOOD JOHNSTONE asked the Secretary of State for Wa whether it was the intention of the War Office to drain the camp at Longmoor into a brook which is a confluent of the river Rother, and if so, whether he would state what precautions would be taken to render the discharge of sewage into that brook innocuous before it reached the Rother; and whether, before any scheme was sanctioned for the disposal of the sewage from this camp the opinion of the Local Government Board would be taken as to the suitability of the scheme and as to how far it might fulfil the requirements which it imposed upon local authorities who had to provide for the disposal of sewage.—Mr. BRODRICK replied: It is no contemplate [illegible] into any brook o river. The [illegible] ment on approved principles a [illegible] d, be subjected to land treatment in accordance with [illegible] Government Board.

Appointments.

Successful applicants for Va [illegible] Public Institutions and others possessing [illegible] this column, are invited to forward to [illegible] ected to the Sub Editor, not later than 9 [illegible] morning of each week, such information for gratuitous publication.

BALDWIN, G. P., L.R.C.P. & S. Edin., has been appointed a Member o the Military Pension Board, New Zealand.

BEAUMONT, PERCIVAL, M.B. Cantab., has been appointed Physician t the Essex and Colchester General Hospital.

COPLANS, MYER, M.B. Lond., has been appointed Resident Medical Officer to the North-West Lond [illegible] Kentish Town road, N

EATON, OLIVER, L.R.C.P. Lond., [illegible] s been re-appointed Medical Officer of [illegible]

FLECK, DAVID, M.B., B.Ch., B.A.O. [illegible] appointe Resident Superintendent to the Royal Victoria Homes at Brentry near Bristol.

HARRISON, W. A., M.B., Ch.M. Edin., has been appointed Acting District Medical Officer, Williams, Western Australia, during th absence on leave of Dr. Roughan.

HAYWARD, WILLIAM THORNBOROUGH, M.R.C.S., has been appointe on the Board of Management of the Adelaide Hospital, South Australia.

HILL, ALFRED WILLIAM, M.D. Brux., has bee [illegible] of Management of the Adelaide Hospita [illegible]

ICK, T. E., M.B. Melb., has been appointed [illegible] Hill, Western Australia.

KING, F. W. R. J., M.R.C.S., L.R.C.P. Lond., has been appointed Member of the Military Pension Board, New Zealand.

MORRIS, M. E. H., M.B. Lond., has been appointed House Surgeon t the North Devon Infirmary, Barnstaple, vice Mr. R. Cook resigned.

PENBERTHY, WILLIAM, L.R. [illegible] has been appointe Medical Officer, Public [illegible] Deaths for the Wivelisco [illegible] Board of Guardians, vice [illegible]

ROGERS, RICHARD SANDERS, [illegible] on the Board of Management [illegible] Australia.

SHEPHERD, ARTHUR EDMUND, L.R.C.P., L.R.C.S. Edin., has bee appointed Honorary Gynæcologist, Adelaide Hospital, Sout Australia.

SMITH, JOHN CARMICHAEL, L.R.C.P. & S. Edin., has been appointe Public Vaccinator at Taihape, New Zealand.

TELFORD, E. D., B.C. Cantab., F.R.C.S. Eng., has been appointe Resident Surgical Officer at the Manchester Royal Infirmary, vic Charles Roberts, M.B. Lond., F.R.C.S. Eng., whose period o appointment has expired.

THOMPSON, JAMES, M.B., Ch.B. Melb., has been appointed Actin District Medical Officer at Busselton, Acting Quarantine Offic for the port of Busselton, and Acting Public Vaccinator for th Urban and Suburban Districts of Busselton and Rural District o Sussex, [illegible]

WACE, R. I. [illegible] has been appointed a Visitin Justice t [illegible] estern Australia.

Vacancies.

For further information regarding each vacancy reference should b made to the advertisement (see Index).

AYLESBURY, ROYAL [illegible] HOSPITAL.—Resident Surgeon unmarried. Sal [illegible] d and apartments

BECKETT HOSPITAL, [illegible] House Surgeon Salary £100, with board, lodging, and washing.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Male House Surgeon Salary £80 per annum, with board and washing.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, John Bright-street, Birmingham.—Clinical Assistant Honorarium at rate of 52 guineas per annum.

BIRMINGHAM GENERAL DISPENSARY.—Resident Locums. Term 4 guineas per week, with apartments.

BRISTOL GENERAL HOSPITAL.—Surgeon, also Assistant Surgeon.

CHESTER GENERAL INFIRMARY.—House Physician. Salary £90 pe annum, with residence and maintenance.

CROYDON MENTAL HOSPITAL, Warlingham, Surrey.—Senior Assistan Medical Officer. Salary £160 per annum, rising to £180 per annum with apartments, board, and washing.

DUDLEY GUEST HOSPITAL.—Assistant House Surgeon, for six months Salary £40 per annum, with residence, board, and washing.

EVELINA HOSPITAL FOR CHILDREN, Southwark, S.E.—Four Clinical Assistants.

GUARDIANS OF THE POOR OF ST. MARY, ISLINGTON.—Medical Officer and Public Vaccinator for No. 1 District. Salary £100 per annum, with fees.

ISLE OF WIGHT COUNTY HOSPITAL, Ryde.—Resident House Surgeon. Salary £90 per annum.

KENT AND CANTERBURY HOSPITAL.—House Surgeon, unmarried. Salary £90 a year, with board and lodging.

LIVERPOOL EYE AND EAR INFIRMARY.—House Surgeon. Salary £80,

0

8, Hunter-street, Brunswick-square, W.C.—Second Demonstrator of Anatomy.

MONKWEARMOUTH AND SOUTHWICK HOSPITAL, Sunderland.—House Surgeon. Salary £80 per annum, with board, lodging, and washing.

METROPOLITAN ASYLUMS BOARD ASYLUM, Caterham, Surrey.—Male Assistant Medical Officer, unmarried. Salary £180 per annum, rising to £200, with rations, lodging, attendance, and washing.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £160.

with board and washing.

UNIVERSITY COLLEGE, London.—Assistant Physician.

WARRINGTON INFIRMARY AND DISPENSARY.—Senior Resident House Surgeon, unmarried. Salary £120 per annum, with residence and board.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodging, washing, and attendance.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician,

WIG Y AND DISPENSARY.— board, apartments, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £120 a year, with board, lodging, and attendance.

Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PROBABLE NATURE AND LIFE CYCLE OF THE YELLOW FEVER GERM.

DR. CARLOS FINLAY, chief sanitary officer of Cuba, has published in

ect of

He

the

non-immune human being and the other a species of mosquito, and concludes that the germ, like that of malaria, must be a protozoon and not a bacterium. He is led also by analogy to infer that the germ of yellow fever goes through phases of development similar to those of the malaria parasite. He endeavours to show that while the human subject is rightly considered as the permanent host for the germ of malaria it is the stegomyia mosquito which acts the part of a permanent host for the yellow fever germ, the short sojourn of which in the body of the yellow fever patient is such as might be expected of a parasite going through phases of sexual reproduction in the body of its intermediate host. Comparing the known facts regarding the clinical history, etiology, and epidemiology of yellow fever, the striking circumstance is not the parallelism but rather the contrast between the course of events in malaria and in yellow fever. He states the following practical deductions as the outcome of the views expressed in the paper.—

1. The yellow fever germ being the parasite of a small insect must be a much smaller protozoon than the malaria germ which is a parasite of man.

2. The reality of ultra microscopic germs as promoters of human infectious diseases having now been scientifically demonstrated, it is possible that the germ of yellow fever may be one of that class.

3. For other infectious diseases the germs of which have escaped detection it may be surmised that the germs are, or at one time were, parasites of a very diminutive insect host which either continues unsuspected or may have become extinct.

4. The sojourn of the yellow fever germ in the human body is of short duration, in accordance with its object, which is mainly to secure the preservation of the species by sexual reproduction.

5 The function of sexual reproduction is accompanied by the elaboration of powerful toxins to which must be directly attributed the attack of yellow fever.

6. Apart from the elimination or destruction of the mosquitoes our main reliance for the prophylaxis of yellow fever and malaria should consist in preventing the transfer of the parasite from the intermediate host to the permanent one; this is comparatively easy in yellow fever but for malaria presents almost insurmount-

In the same publication (*Revista de Medicina Tropical*) Dr. Juan Guiteras, professor of pathology and tropical medicine in the University of Havana, contributes a paper on the Duration of Life of *the Stegomyia* Fasciata or Yellow Fever Mosquito. He says that as this insect retains its infectivity during all its life the facts which refer to the duration of its life are of great interest. From an experiment made at the laboratory it appears that of 11 mosquitoes hatched on August 1st, 1902, which were made to bite on the 5th of the same month a patient with yellow fever no less than five mosquitoes lived over 100 days and one as long as 154 days. These mosquitoes were preserved in a wide-mouthed *glass jar covered* with gauze; inside the jar were placed a glass of water, some grass, and a lump of sugar. Dr. Finlay and others have proved that the life of the mosquito is short (a few days only) if it is deprived of water, but Dr. Guiteras thought that in a state of hibernation the insects could perhaps live without water. He therefore retained in a wire gauze cage 33 female stegomyiæ without water, grass, or sugar. They were placed in an ice-box having a temperature between 8° and 10° C. 45 days later 16 mosquitoes survived and at the eighty seventh day three were still living. The same writer has made some *observations on the Shiga Bacillus* and Secondary Infections in Yellow Fever. In one case of yellow fever, on the fifth day of the disease a decided agglutination of the Shiga bacillus (belonging to the group of hæmorrhagic bacteria) was obtained in 20 minutes with dilutions of 1 in 50. The patient died on the *fourteenth* day and continued to the end to give the Shiga reaction and to show hæmorrhagic symptoms. Dr. Guiteras suggests that it is possible that this secondary infection may account for some of the symptoms of the disease, such as the hæmorrhages and the remissions of the fever.

A REFLECTING CRYPTOSCOPIC "CAMERA" FOR X-RAY WORK.

IN the New York *Electrical Review* of May 23rd Mr. William Rollins publishes a copiously illustrated article on some pieces of apparatus which he calls "*reflecting* cryptoscopic cameras." He states that he described the first reflecting cryptoscope and the first cryptoscopic camera in the *International Dental Journal* for July, 1896. In the present article he gives an account of two forms of this instrument, one of them being intended for examination of the feet and the other for examination of the body of a person in the horizontal position. The first of these somewhat resembles an ordinary portable writing-desk the slope of which rises more rapidly than usual. A photographic plate-holder and a fluorescent screen can be held against the under side of the slope, the plate-holder being always above the screen. A horizontal mirror lies on the bottom of the camera face upwards, so that when a foot is placed on the slope and a source of x rays is brought over it, an observer looking downwards through the side of the camera into the mirror sees the image of the foot displayed on the screen, and in this way, before placing a sensitised plate in the plate-holder, he can move the foot as may be required and can also arrange the position and direction of the light. During the exposure of the plate it may be useful to view the image produced on the screen by the rays which have traversed the plate. The other camera is hung on side rails attached to the table on which the person to be examined is lying in the horizontal position. It can, therefore, be slid under the table to any required point and the observer looking downwards into the mirror sees on the screen the image of any part which is to be inspected. The plate-holder with the sensitised plate is then introduced above the screen as before.

THE SURGEON AND THE CARPENTER.

(*With due apologies.*)

THE following lines have been sent to us as suggested by an address recently printed in our columns:—

The Surgeon-and-the-Carpenter
  Was walking down the Strand
(The Surgeon and the Carpenter
  Are one, you understand;
The Surgeon is the master Mind,
  The Carpenter's the Hand).

"If things go on at such a pace,"
  I heard the Surgeon say,
"Each member of the human race
  Will meet the knife some day:
A terrible catastrophe."
  The Carpenter said "Nay."

"At present, too," the Surgeon said,
  "Physicians are so proud,
To back my own opinion
  I scarcely am allowed;
Yet mine, perhaps, is worth as much
  As any of the crowd.

"They seem to think," he hurried on,
  "That I am only you,
And that they have a right to say
  What I have got to do;
That they design the Surgeon's work
  And we just 'put it through.'

Now, when you reach a certain stage,"
  He further made remark,
"You grow incomparably sage"—
  "Excuse me, here's the park,"
The Carpenter observed, "and see
  It's very nearly dark."

The Public, who was looking on,
  Meandered home to tea,
It talked about the Surgeon's words
  And what he meant to be;
And said, "If he's no Carpenter,
  What use is he to me?"

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any reader could recommend a peaceful home for a lady suffering from naso orbital sarcoma. The home should be very comfortable and situated in beautiful country surroundings with large private grounds so that the patient could take carriage exercise unobserved in the grounds. Kent would be preferred, but any part within a few miles of Chatham would do. Accommodation would also be necessary for the nurse. The relatives would like to find lodgings or an hotel close to the home so as to be able to be with the patient all day.

I am, Sirs, yours faithfully,

June 5th, 1903. A. G.

"H. V. M." would like to know if there is any home for epileptics for the very poor unable to pay more than 2*s.* or 3*s.* weekly.

THE GENERAL MEDICAL COUNCIL AND THE SOCIETY OF APOTHECARIES.

To the Editors of THE LANCET.

SIRS,—In your account of the proceedings of the General Medical Council on May 23rd, reported in THE LANCET of May 30th, p. 1559, Mr. Brown is reported as saying, regarding the Society of Apothecaries, that "it was its statutory duty to provide qualified dispensers for medical men, but this had not been done," &c. Now, the society does provide qualified dispensers, but so many medical men employ *un*qualified dispensers (no doubt because they are cheaper) that we who are qualified find it difficult to obtain posts at 30*s.* per week.

I am, Sirs, yours faithfully,

June 7th, 1903. QUALIFIED DISPENSER.

⁂ Of late years some 300 candidates per annum have presente themselves before the London Society of Apothecaries for examina tion certificates as dispensers. Of these about one-half are foun worthy to receive the certificates. The future of these assistants is so far as we know, as dispensers to medical men, to hospitals, or t public infirmaries, and they find little or no difficulty, as a rule we believe, in obtaining employment.—ED. L.

HYPNOTISM FOR INEBRIETY.

A CORRESPONDENT writes to ask us if any of our readers can supply hi with any information as to the results of hypnotic suggestion in th treatment of inebriety and where such treatment could be unde gone. Will any of our readers who can help our correspondent kindl do so?

◆

An Inquirer.—It is impossible to give any very definite answer to o correspondent on the information supplied. If he will consult o advertisement columns he will be able to form a fair idea of what usually offered.

R. H.—The exaggerated renal action cannot be taken as evidence favour of the sample. Several "all malt" whiskies have recent been analysed in our laboratories and their claims will be fu reported upon in our columns.

Physician.—A reference to our advertising columns will show that t season is from May 1st to Oct. 1st.

COMMUNICATIONS not noticed in our present issue will receive attenti in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *Highland News, Western Daily Press, Evening Leader (Newcastle), Referee, Derbyshire Courier, Derbyshire Times, Reading Mercury, Herts Advertiser, Times of India, Aberdeen Weekly Free Press, Daily Mail, South Wales Echo, Westminster Gazette, Dublin Daily Independent, Dublin Express, Margate and Ramsgate Gazette, Yorkshire Post, Hertfordshire Mercury, Exeter Express, Burnley Express, Dublin Evening Telegraph, Echo, Bradford Observer, Daily Express, Globe, Lincoln Herald, Windsor and Eton Express, &c.*

Communications, Letters, &c., have been received from—

A.—Mr. G. T. Arnold, Torquay; Mr. W. F. Abbott, Folkestone; Messrs. Allen and Hanburys, Lond.; *Archives de Thérapeutique*, Paris; A. S. R.; A. M. D.; Dr. H. Adamson, Beechworth, Australia; A. G.; Apollinaris Co., Lond.

B.—Dr. A. L. Benedict, Buffalo; Dr. Charles E. Beevor, Lond.; Mr. A. H. Burgess, Manchester; Dr. A. T. Brand, Driffield; Mr. Stanmore Bishop, Manchester; T. B. Browne, Ltd., Lond.; Messrs. C. Barker and Sons, Lond.; Messrs. Boulton and Paul, Norwich; Mr. H. T. Bull, Bury; Borough Hospital, Birkenhead, Secretary of; Captain G. D. Browning, R.A.M.C., Alton; Bristol General Hospital, Secretary of; Birmingham City Asylum, Medical Superintendent of; Dr. T. B. Broadway, St. Austell; Birmingham and Midland Hospital for Skin and Urinary Diseases, Secretary of; Bromley, East, Vicar of; Messrs. Burroughs, Wellcome, and Co., Lond.

C.—Cuba, Chief Sanitary Officer of; Messrs. Cosenza and Co., Lond.; Mr. A. W. S. Curties, Wakefield; County Borough of Southampton, Town Clerk of; C. G. S.; Messrs. A. H. Cox and Co., Brighton; Dr. G. E. J. Crallan, Bournemouth; Church Sanitary Association, Hon. Secretary of; Messrs. S. Clark and Co., Lond.; Messrs. T. Christy and Co., Lond.; Dr. A. Campbell, Lond.

D.—Messrs. Davies, Gibbins, and Co., Derby; Denver Chemical Manufacturing Co., Lond.; Mr. G. T. de Fraine, Aylesbury; Mr. J. Q. Donald, Colinsburgh; Mr. Dale, Stockton Heath; Dr. S. J. Dickens, Cowfold; Deaf and Dumb, Association for Oral Instruction of, Secretary of; Mr. M. S. Dodd, Newcastle-on-Tyne; Dermatological Society, Hon. Secretary of.

E.—Captain H. M. Earle, I.M.S., Dharamsala, India; Messrs. Evans, Gadd, and Co., Bristol; Dr. F. W. Edridge-Green, Lond.; Dr. E.; Dr. G. L. Eastes, Lond.; Mr. E. A. Edington, Worthing; An Enquirer.

F.—Dr. T. Fisher, Bristol; Messrs. Fairchild Bros. and Foster, Lond.; Mr. P. Furnival, Lond.

G.—Monsieur M. George, Meudon; Dr. T. R. Glynn, Liverpool; Great Eastern Railway Co., Continental Traffic Manager of; Dr. J. W. Greenwood, Hanley; Rev. H. M. Green, Lond.; Messrs. Graham and Shepherd, Sunderland; Glasgow Southern Medical Society, Secretary of; Sir W. Gowers, Lond.

H.—Mr. H. S. Harris, Esher; Hunterian Society, Hon. Secretary of; Dr. R. Henchley, Canterbury; Dr. T. K. Herschel, Bordighera, Italy; Humanitarian League; Mr. E. J. Hynes, Huddersfield; Mr. W. Hughes, Carnarvon.

J.—Dr. R. Jones, Woodford Bridge; Mrs. W. Johnson, Northallerton; Jansenville, Cape Colony, District Surgeon of; J. S.; Jenner Institute, Governing Body of.

K.—Dr. L. Kidd, Enniskillen; Mr. A. D. Kennard, Hampton Wick.

L.—Dr. D. Lawson, Banchory; Mr. H. K. Lewis, Lond.; Mr. B. M. Lewis, Pontypridd; Captain Clayton Lane, I.M.S.; Lieutenant T. B. Lauder, R.A.M.C., Rangoon; Mr. H. Littlewood, Leeds.

M.—Mr. F. C. Madden, Cairo; Medical Society of Victoria, Melbourne, Hon. Secretary of; Manchester Medical Agency, Secretary of; M. J.; Manchester Royal Infirmary, Secretary of; Dr. E. W. S. Martin, Brithdir; Moseley's Food, Ltd., Stockport; Maltine Manufacturing Co., Lond.; Mr. T Marshall, Lond.; Messrs. H. Muller and Co., Lond.; Monkwearmouth Hospital, Sunderland, Secretary of; Messrs. J. Macfarlan and Co., Lond.

N.—National Dental Hospital and College, Lond., Secretary of; Newport Hospital, Secretary of; North Staffs Infirmary, Stoke-on-Trent, Secretary of; Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.; National Sanatorium for Consumption, Bournemouth, Secretary of.

P.—Dr. M. E. Paul, Alderney; Messrs. C. Pool and Co., Lond.; Mr. Y. J. Pentland, Edinburgh; Pastel Society, Secretary of; Dr. G. W. Parker, Hove; Messrs. S. Pownceby and Co., Lond.; Parish of St. Mary, Islington, Clerk of; Pentonville-road (27), Lond.; Mr. S. Phillips, Lond.; Dr. G. Peacock, Dublin; Dr. J. F. Payne, Lond.

Q.—Qualified Dispenser.

R.—Royal Society, Secretary of; Royal Surrey County Hospital, Guildford, Secretary of; Royal Albert Edward Infirmary, Wigan, Secretary of; Mr. R. Redpath, Newcastle-on-Tyne; Royal Hospital for Women and Children, Secretary of; Mr. R. W. Rees, Llandudno.

S.—Mr. E. Schloesser, Wiesbaden; Messrs. Spottiswoode and Co., Lond.; Mr. H. Smale, Lond.; Messrs. Savory and Moore, Lond.; Shredded Wheat Co., Lond.; Dr. H. Shelmerdine, Bexley Heath; Captain R. Selby, Malappuram, India; Dr. E. W. Samways, Brides-les-Bains; Miss Shepherd, Gersau; Scholastic, Clerical, &c., Association, Lond.; Mr. E. Schweizerbart, Stuttgart; Mr. J. A. Smyth, Lond.; Mr. B. S. Story, Durham.

T.—Dr. E. Trevithick, Cheltenham; Dr. J. C. Thresh, Chelmsford.

V.—Vinolia Co., Lond.

W.—Messrs. W. Watson and Co., Lond.; West Bromwich District Hospital, Secretary of; Messrs. Wright, Dain, and Co., Birmingham; Mr. B. Wheeler, Manchester; Messrs Willing, Lond.; Messrs. R. F. White an Son, Lond.; Mr. J. Ward, Lond Dr. G. Morton Wilson, Conway Mr. J. Wanamaker, New York Messrs. H. Walker and So Lond.; Dr A. Whitfield, Lond Dr. R. Wilkinson, Norwood Dr. F. J. Waldo, Lond.

Letters, each with enclosure, are also acknowledged from—

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

The Croonian Lectures

ON

MUSCULAR MOVEMENTS AND THEIR REPRESENTATION IN THE CENTRAL NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London

BY CHARLES E. BEEVOR, M.D.,
F.R.C.P. LOND.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC AND THE GREAT NORTHERN HOSPITAL.

LECTURE I.

Delivered on June 9th.

MR PRESIDENT AND GENTLEMEN,—I have first to express to you, Sir, and to the Council of this College, my most sincere thanks for the great honour which you have conferred on me in selecting me to deliver the Croonian lectures. I feel very deeply the responsibility of undertaking this duty and when I regard the roll of distinguished Fellows who have preceded me, my task is indeed difficult, and though I fear that I shall not attain the higher standard which they have set, my endeavour will be to lay before you to the best of my ability some investigations on muscular movements on which I have been working for some years. The choice of my subject will also, I think, be in harmony with the wishes of the founder of these lectures, for while the Croonian lectures at this College are directed to be given on one or more subjects in anatomy, physiology, and pathology, with a view to the prevention, control, and cure of disease, the Croonian lecture to be delivered annually before the Royal Society is required to be on the nature and laws of muscular motion. So that we may infer that the founder himself took a great interest in the muscular system.

In taking the subject of muscular movements the first question which would naturally arise is: Which is the best method to ascertain the action of a muscle? To determine the action of a muscle there are three chief methods—first, the anatomical method, which is employed on the dead subject and consists in dissecting out a muscle, freeing it from its connexions, but leaving it attached at its origin and insertion. The muscle is then pulled upon by the dissector and the resultant position of the limb is taken to show the action which the muscle would exercise during life. Or a muscle is seen to have a certain origin and insertion, so that if it contracted it must produce an approximation of the two parts. As an instance of this may be mentioned the inspiratory action of the latissimus dorsi muscle which from its origin from the lowest three or four ribs and its insertion into the humerus has been looked upon as a muscle of forced inspiration, for it was concluded that if when the humerus was fixed the muscle contracted its only action would be to elevate the ribs, whereas its chief aim is expiratory, as we shall see later. This—which I have called the anatomical method—is the only means which we have of obtaining knowledge of the action of muscles too deeply seated to be examined during life, such as the quadratus lumborum and the external rotators of the hip-joint It has, however, the following great disadvantages. It gives the action of the individual muscle and thereby leads one to imagine that this particular muscle acts by itself. It gives all the possible actions of a muscle and postulates that in all these possible actions the muscle must take part. With regard to these objections I think that there is hardly an instance in the whole body of a movement in which only one muscle takes part and it would therefore be necessary to know the particular share of the other muscles in the movement and the manner in which they affect the action of the muscle under consideration. It does not follow because a certain movement can be produced on a joint by traction on the dissected muscle that therefore the muscle must be used during life for this movement, as it may not be advantageous to use the muscle for this purpose.

The second, or electrical method, is the one which was employed by Duchenne with such great success and his classical observations on the actions of muscles will always rank as one of the most brilliant achievements in the subject. The method consists in faradising with the two poles of an induction coil the muscle under examination and then noting the action produced on the joint or joints over which the muscle acts. The results of this method have given most valuable information as to the action of the muscles, and where the muscles are superficial enough to be reached by the current this method is much preferable to the anatomical method in that the movements are produced by the living muscle undisturbed in its relation to surrounding parts. I venture to think, however, that this method is open to the same objections as the anatomical method in that although every movement that the muscle is capable of is undoubtedly produced, yet as the muscle does not act alone we do not know what the influence of the other muscles may be which also enter into the movement, and also there is the second objection that we do not know by this method whether a muscle which on stimulation gives the movement, let us say, of supination is included in the movement of supination, when this is performed as a voluntary act.

It seems to me that although these two methods will tell us what a muscle may do it does not tell us what a muscle does do, and we cannot say for certain that a muscle has a definite action without following the precept of the immortal Harvey, and going direct to nature and there testing the results obtained by the anatomical and electrical methods. This last method, which we call the physiological or natural method, differs from the first two in reversing the order of procedure. In the anatomical and the electrical methods one muscle is taken and by dragging on it or stimulating it to contract certain movements are produced; whereas in the physiological method a living person is told to perform a definite movement and it is then observed which muscles take part in this movement.

Certain precautions have to be taken in using this method, the most important being that the person shall perform by fixation of the limb the movement only which is required, so that, for example, if a person is told to pronate the forearm he must not at the same time abduct the shoulder and thereby bring into action other muscles than those concerned directly with pronation. The means which I have used for determining whether a muscle is taking part in any given movement are inspection and palpation either of the muscle as a whole or of its tendon. I have examined both normal people and patients who have lost the use of some of their muscles. The movements have been performed in three ways: (1) by moving the limb only without any extra weight; (2) by moving the limb loaded with different weights; and (3) by attempting to move the limb which is fixed by an opposing force. The first procedure gives the minimum work which the muscles entering into any movement are called upon to do. The least possible work that a group of muscles can do is to overcome the inertia of a joint. This can be accomplished in the elbow by placing the upper arm on a support in a horizontal position and then flexing or extending the forearm on it in a horizontal plane; by this means the action of gravity can be neutralised. Or with the upper arm resting horizontally the forearm can be placed vertically and the movements of pronation and supination can be carried out. The next degree of work is that afforded by lifting the limb against gravity, as in flexing the forearm when the humerus is in the vertical position alongside the trunk. The third procedure gives the greatest work that the muscles can perform and as by reason of the fixation of the limb there is no alteration in the angle of the joint the error is avoided of assuming that the tightening of a tendon from the stretching of a passive muscle is evidence of contraction of the muscle. The second method would give the intermediate conditions between the two extremes of maximum and minimum work. The amount of work done by the muscles was measured by spring balances or by the traction scale of a clinical dynamometer.

With the exception of Winslow[1] and Duchenne I am unable to find that writers on anatomy as a rule take their knowledge of the action of muscles from the living subject. James Benignus Winslow, whom Duchenne rightly styles the "Admirable Winslow," and who, although his name has an English sound, was professor of physic, anatomy, and surgery in the University of Paris in the eighteenth century, speaks with no uncertain note when he writes that "the Experiments made on dead Bodies, by pulling the muscles after they have been raised, are very fallacious." There are lists of muscles which are given under the different heads of flexors, extensors, rotators, abductors, adductors, &c., but how are these lists obtained? They are made by putting into one category, for instance, all the single muscles which are labeled flexors, &c., and such a list does not express a combination which has been verified by actual inspection during life. I venture to think that, if all the muscles contained in some of these lists contracted the movement produced would not be the one which is expected and I trust to be able to show that the actions which are ascribed to some of the muscles cannot be substantiated when put to what I think will be admitted to be the only true test—their actions in the living subject. In examining a case of muscular atrophy the chief difficulty consists of knowing what movements to ask the patient to perform in order to find out whether a particular muscle is acting or not. I trust that the time will come when the actions of muscles will be taught on the living subject together with the part which they take in the performance of simple movements.

---

[1] An Anatomical Exposition of the Structure of the Human Body, by James Benignus Winslow. Translated from the French original by G Douglas, M D. Fourth edition, corrected. 17[illegible].

I now propose to take the movements of some of the joints of the body and to describe the muscles which take part in producing the movements as observed in the living subject. For convenience I shall begin with the movements of the upper limb. I shall use in all cases the Latin names for the muscles and I would like here briefly to express my regret in these days, when the idea of a universal language is so much discussed, that in anatomy so many nations prefer to use the vernacular instead of the Latin name which is intelligible to everyone. For instance, the serratus magnus is described in foreign modern anatomical works as the "grand dentelé" and the "vorderer Sägemuskel," and when we come to the anatomy of the brain the corpus geniculatum externum becomes the "corps genouillé" in French and the "äusserer Kniehöcker" in German. I am glad to say that in this country we have not followed this practice and that we do not talk as yet of the "front saw muscle" or the "outer knee-knob." It would save much trouble if every nation adopted the Latin terms, a decision which I believe the International Nomenclature Committee has arrived at.

Taking some of the movements of the upper limb, and beginning with those of the fingers, I would remind you that the first phalanges of the fingers are flexed on the metacarpal bones by the interossei and lumbricales, an anatomical discovery which was made by Columbus and Fallopius in 1559 and 1561 and which, according to Duchenne, was lost sight of till he (Duchenne) again called attention to it, but this is hardly correct as it was already mentioned by Winslow,[2] and John Hunter[3] refers to it in his Croonian lecture delivered before the Royal Society in 1777. The first phalanges are also flexed by the tendons of the flexores digitorum on their way to the terminal digits. If, however, it is required to flex the last two phalanges of each digit, but not the first, the extensor communis digitorum is brought into action—a muscle which extends the first phalanx more than the last two phalanges. If the movement of flexion of the fingers is required without any movement of the wrist, then along with the flexores digitorum the extensores carpi radialis longior and brevior and ulnaris contract.

The extension of the second and third phalanges is, as is well known, produced by the two sets of muscles, the extensor communis digitorum and the interossei and lumbricales which are inserted into the common extensor tendons. The action, therefore, of these small muscles is to flex the first phalanx and to extend the second and third phalanges. Duchenne[4] is strongly in favour of the theory that the action of the extensor communis digitorum on the last phalanges is exceedingly limited and that it is not an extensor of all the phalanges but that it only has a true action on the first phalanx and he proposes to call it the extensor of the first phalanx. He also states in another part of his book, "Physiologie des Mouvements," that the interossei and lumbricales are in reality the sole extensors of the last two phalanges and the sole flexors of the first phalanx. It is no doubt true that when the extensor digitorum is paralysed the last two phalanges can be extended by the interossei and lumbricales and also that in the "claw-hand" there is inability to extend the last digits when these small muscles are paralysed. In the latter case if the first phalanges be kept passively flexed on the metacarpus, then the person is able to extend the terminal digits, so that it seems probable that the inability of the extensor digitorum to extend the terminal phalanges is due to its energy being expended on the first phalanges which are not prevented from extending by the interossei and lumbricales which are now paralysed.

The extension of the proximal phalanges on the metacarpus by the extensor communis digitorum is accompanied, as Duchenne[5] pointed out, by contraction of the flexors of the carpus—viz., the flexores carpi radialis and ulnaris and palmaris longus. In lead poisoning where there is paralysis of the extensor communis digitorum and not of the extensores carpi the patient can, if he keeps his fingers flexed, extend the hand on the forearm, but if he wishes to extend his fingers, his first phalanges remain immoveable and his hand is flexed on the forearm with as much energy as he makes in his greatest effort to obtain extension of the fingers. The explanation of this combination will be discussed later when we consider the synergic action of muscles.

The lateral movements of the fingers are adduction toward the middle finger and abduction away from the line of the middle finger. Adduction is performed by the palmar interossei and abduction of the three large fingers by the dorsal interossei, but with abduction of the index finger and the little finger other muscles come into action. It is exceedingly difficult to abduct the index finger without adducting or flexing the thumb, from the fact that the first dorsal interosseus or abductor indicis arises from the metacarpal bone of the thumb as well as from that of the index finger, so that if it is required to abduct the index finger alone the extensores ossis metacarpi and primi internodii of the thumb are called into action to prevent the thumb moving. Abduction of the little finger is performed by the special abductor minimi digiti, but as this arises from the pisiform bone this latter has to be fixed by the flexor carpi ulnaris. To obviate the special action of the flexor carpi ulnaris on the wrist the extensor ossis metacarpi pollicis contracts and when the hand is in a line with the forearm it is apparently impossible to abduct the little finger without the extensor ossis metacarpi contracting; if, however, the hand be first adducted to the ulnar side the contraction is less marked.

The movements of the thumb are flexion and extension and take place in a plane parallel to the palm of the hand, of all three joints of the thumb, and also abduction and adduction of the metacarpo-carpal joint in a plane at right angles to the one just mentioned. In addition there is opposition of the thumb to the fingers. Now with regard to the movements of the first metacarpus on the carpus, in the movements of flexion and extension which take place in a plane parallel to that of the palm of the hand the palmar surface of the thumb is at right angles to the palm of the hand, but in the movement of abduction it seems to me that it is difficult to perform this movement without rotating the thumb inward so that the palmar surface of the thumb is opposed to that of the fingers. Therefore in abducting the thumb it passes naturally into the position of opposition and from that position it can be advanced towards the tips of the fingers in succession, but more rotation will be required to oppose it to the index finger than to the fourth finger. Taking the terminal phalangeal joint of the thumb first, flexion, as is well known, is performed by the flexor longus pollicis and if this movement alone be required the extensor primi internodii contracts to prevent the first phalanx being flexed on the metacarpus. Extension of the last phalanx is performed by the extensor secundi internodii pollicis, but, as was pointed out by Duchenne, this simple movement cannot be performed without also calling in the action of the abductor pollicis, the flexor brevis pollicis, and the adductor pollicis, as these small muscles send prolongations to the tendon of the extensor secundi internodii (Sabatier, Bouvier, and Duchenne), so that by the action of these small muscles the last phalanx can be extended without extending the first phalanx.

The movements of the metacarpo-carpal joint of the thumb are more complicated and besides flexion and extension there is opposition. Flexion of the metacarpal bone of the thumb is caused by the opponens pollicis and by the abductor flexor brevis and adductores pollicis, transversus and obliquus as they are now called, when flexion of the first phalanx is also required, but when flexion of the metacarpal bone is required with extension of the phalanges there is also some action of the extensor primi internodii pollicis. Flexion of the metacarpal bone is also effected by the flexor longus pollicis after the metacarpal joints are flexed. Extension of the metacarpal bone is performed by the extensor ossis metacarpi and also by the extensor primi internodii. At the same time, as was pointed out by Duchenne, it is not possible to extend the metacarpal bone and the first phalanx of the thumb without putting into action the extensor carpi ulnaris and also, I would add, the flexor carpi ulnaris, which, however, does not come into action so soon as the extensor. The reason why these muscles are brought in will be discussed later; at present I would lay stress on the impossibility of extending the thumb without putting these other two muscles into action and also that this action occurs in all positions of the wrist even when it is in that of extreme abduction, a position in which it would not be possible for the extensor ossis metacarpi to move the wrist further in the direction of abduction.

---

[2] Loc. cit., vol. i., sect. iii., No. 966.

[3] The Works of John Hunter, F.R.S., 1837.

[4] Physiologie des Mouvements, 1867, p. 164.

[5] Loc. cit., §§ 168, 169.

Abduction of the thumb is performed by the small thumb muscles—viz., the abductor pollicis, opponens pollicis, and outer head of the flexor brevis, and also by the extensor ossis metacarpi and primi internodii. This is not in accordance with Duchenne[6] who from electrical observations states that the extensor ossis metacarpi is one of the opposing muscles of the thumb and not its abductor, while the extensor primi internodii is not an extensor of the first metacarpal but is the only direct abductor. If by abduction is meant carrying the thumb away from the first finger in a plane at right angles to the palm I think that there is no doubt that the tendons of both these two extensors of the thumb can be felt to contract. There is one important point with regard to this movement and that is that though it is possible to abduct the thumb when the extensors of the thumb are paralysed it is quite impossible for the extensors of the thumb to abduct in the slightest degree when the small thumb muscles are paralysed; in fact, inability to abduct the thumb is one of the best tests for the absence of the small muscles of the thumb. In adduction of the thumb from the position of abduction it rotates from within outwards and this movement is performed by the adductor transversus and probably the obliquus and by the extensor secundi internodii, as shown by Duchenne. When, however, the thumb has passed the middle point of its movement I find that the flexor carpi ulnaris also contracts, probably to counteract the extension of the wrist by the extensor secundi internodii. Opposition is best performed after abducting the thumb and from that position advancing it to meet the fingers; the muscles which take part in this movement are the abductor pollicis, the opponens pollicis, the flexor brevis, and the adductores pollicis. According to Duchenne[7] the abductor chiefly opposes the thumb to the first two fingers and the flexor brevis to all the fingers, while he also includes the extensor ossis metacarpi, which, according to him, is one of the chief opposers of the metacarpal bone and not its abductor; but it seems to me that although it does act in abducting the thumb and putting it in the position of opposition it ceases to act as soon as any resistance is made to the opposition. The movement of opposition is therefore preserved when the extensor ossis metacarpi is paralysed and lost when the thenar muscles are paralysed. It is interesting to note that Duchenne[8] from electrical observations ascribes to the adductor pollicis four different movements on the metacarpal bone of the thumb—viz., adduction, abduction, extension, and flexion. With this I am not able to agree as I cannot find that the muscle takes part in abduction or extension in any position of the bone and I think it is an instance where the actions obtained by electrical stimulation of a muscle do not find their counterpart in the voluntary movements in the living It postulates that a muscle may act as a primary in two movements which are diametrically opposed t other, a condition which I believe does not exist in the human body and which I shall refer to later.

We have next to consider the combined movements of the fingers and thumb, as in grasping an object. Here all the muscles which flex the different joints of the fingers and thumb come into action and in addition to these muscles the extensors of the wrist take part in the action just as they take part in that of flexion of the first phalanges of the fingers. This combination was definitely pointed out by Duchenne[9] who stated "that the synergic action of the extensors of the wrist is absolutely necessary to the flexion of the fingers and the force of their contraction is then proportional to the energy of this flexion."

The movements of the wrist are flexion, extension, radial lateral movement or abduction, and ulnar lateral movement or adduction. In addition to the definite flexors of the wrist—viz., flexor carpi radialis, flexor carpi ulnaris, and palmaris longus—the flexors of the fingers become also flexors of the wrist, but this depends on where the resistance is made. If the resistance is made against the phalanges then the flexores digitorum do flex the wrist after they have flexed the fingers, but if resistance is made against the metacarpal bones so that only pure flexion of the wrist is required then the flexors of the digits contract. With regard to the muscles of the thumb, the extensor ossis metacarpi, as stated by Duchenne,[10] is a flexor of the wrist. Extension of the wrist is performed by the three extensors of the wrist and also by the extensor secundi internodii to a slight degree but not by the other two extensors of the thumb. The question of the part played by the extensors digitorum will be discussed presently. Abduction of the wrist is performed by the flexor carpi radialis, the three extensors of the thumb, and the extensor radialis longior, and adduction by the flexor carpi ulnaris and the extensor carpi ulnaris. It is interesting to note that Duchenne[11] from electrical stimulation denies that the flexor carpi ulnaris is an adductor or that the flexor carpi radialis is an abductor of the wrist. In reply to that I would say that in performing the movement of adduction and abduction these muscles can be felt to contract and it shows how important it is that results obtained by electric testing should be verified by reference to the living body. The action obtained by electrical stimulation is that of the muscle acting alone, a condition which does not exist in the body unless all the other muscles are paralysed. In passing round from the movement of flexion of the wrist to adduction the flexor carpi ulnaris is either contracting with the palmaris longus in flexion or with the extensor carpi ulnaris in adduction. It is quite possible that if this last muscle, the extensor carpi ulnaris, were absent the flexor carpi ulnaris would not be able to adduct the wrist alone. Now, according to Duchenne[12] faradisation of the extensor carpi radialis longior and of the extensor carpi ulnaris alone produces extension with abduction and adduction respectively, so that these two muscles acting alone could not produce pure abduction or adduction; to do so each must act with the flexor carpi radialis and ulnaris respectively.

In reference to the movements of extension and flexion of the wrist an important question arises as to the part taken by the extensors and flexors of the fingers in this movement. It is mentioned by Duchenne,[13] and whether he was the first to point it out I do not know, but it is an observation which has been frequently confirmed, and I have already referred to it in speaking of the synergic action of the extensors of the fingers and the flexors of the wrist, that in lead paralysis affecting the extensor communis digitorum, but not the extensores carpi, as long as the person keeps his fingers flexed he can extend with force his hand on the forearm. But if he should wish to extend his fingers his first phalanges remain immoveable and his hand is flexed on the forearm with as much energy as the efforts he makes to produce extension of the fingers. Sir William Gowers[14] in his work on "Diseases of the Nervous System" states in speaking of lead paralysis, in which the extensores digitorum are paralysed but not the extensores carpi, that "as long as the special extensors of the wrist retain power this joint can still be extended when the fingers are flexed so as to close the fist, although the wrist cannot be extended when the fingers are also extended. The reason for this seems to be [illegible] When in health the hand and fingers are both [illegible] nsors of the wrist act very little if at [illegible] wrist joint is effected by the long extensor of the fingers; if, however, the fingers are flexed the extension of the wrist is effected by the special extensors." So that, according to Duchenne, if a person with paralysis of the extensores digitorum tries to perform the movement of extending his fingers the only result he obtains is flexion of the wrist, and according to the extract just given a patient with paralysis of the extensores digitorum has no power to extend the wrist as long as he tries to do it with the fingers straight. These conditions are frequently met with in cases of lead paralysis.

Now, the problem which is before us and which has, so far as I know, never been explained is: Why do not the extensors of the wrist, which in this case are healthy, come to the rescue and help the paralysed extensors of the fingers to extend the wrist? They certainly do *not* contract and there must be some explanation of the inability of the person to make them do so. Now, let us observe what happens in the normal condition. With the fingers flexed so as to form a fist, if the wrist be required to be extended, the work is done by the three extensores carpi and their tendons at the wrist and especially the extensores carpi radialis longior and ulnaris can be felt to contract. If now in the course of this extension the fingers be suddenly extended, the extensors of the carpus immediately cease to contract and the work of extension is done by the extensors of the fingers. But the extensors of the fingers cannot act without at the same time causing the flexors of the wrist to contract and by putting one's thumb and finger on the tendons respectively of the extensor carpi radialis and the flexor carpi ulnaris it will be found that when the fingers are extended the extensor carpi can be felt to relax and the flexor carpi ulnaris to contract. The wrist can therefore be extended fully by the extensors of the fingers without the help of the extensors of the wrist, but as the extensors of the fingers have to do this against the contraction of the flexors of the wrist there is a feeling of constraint. Now what will happen if strong resistance be made to the extension of the wrist when this movement is performed by the extensors of the fingers, which are weak muscles; will the extensors of the wrist—so to say—come to the rescue and take part in the movement of extending the wrist? As a matter of observation I have found that they will come and help. But—and I think that this is a most important point and one which I believe has not been shown before—as long as the fingers remain extended, the extensors of the wrist will not help until a certain resistance has been reached and when this amount of resistance is reached the extensor tendons of the wrist can be felt to contract. On the other hand, if the extensors of the fingers retire from the contest and let he fingers flex, the extensors of the wrist instantly contract, no matter how slight the resistance may be. It therefore seemed to me important in extending the wrist by means of the extensors of the fingers to find out, first, the amount of resistance necessary to cause the extensores carpi to contract; and, secondly, the amount of resistance necessary to cause the flexores carpi to cease contracting. The experiment was made with the forearm placed on the flat surface of a table with the palm downwards and with the hand projecting beyond the edge of the table in a line with the forearm, with the fingers extended. Resistance was applied in one of two ways: in the one by passing a broad band over the extended fingers, taking care to keep it beyond or peripherally to the metacarpo-phalangeal joint and then to attach this band to a fixed point with a dynamometer interposed. Against this fixed point the person extended the wrist-joint while the finger of the observer was placed on the tendon of the extensor carpi radialis longior. The other method consisted of keeping the fingers extended and by means of an assistant increasing the traction on the hand until the tendon of the extensor carpi could be felt contracting. The latter was found to be the better method, as the wrist being fixed it was more easy to insure that other movements should not be made which would prevent the tendon being felt. The result of several examinations showed in my own case that the pressure of from three to four pounds was required to be applied to the extended fingers before the extensor carpi radialis longior could be felt to act.

It might be thought that the flexores carpi would cease to contract as soon as the extensores carpi took up the work. But this was not found to be the case, and in some cases more pressure was required, as much as 10 pounds having to be applied before the tendons of the flexores carpi relaxed. The relaxation of the flexors of the carpus is a much more difficult matter to determine, as in some trials they seemed to leave off contracting at once, while in others they were still contracting even with a pressure strong enough to overcome the resistance of the wrist. I think that the following is the explanation. If the fingers be actively extended to the full amount, or if they be quickly extended, the flexors of the wrist are felt to contract synergically and if in this condition pressure be made against extension of the wrist the flexors of the wrist will not relax; but if the extension of the fingers be made very slowly and not to the full degree the flexors of the wrist will hardly be felt to contract or very slightly and in that condition very little pressure against the extension of the wrist suffices to relax them altogether. It therefore appears that if the predominant idea is extension of the fingers, then the flexors of the wrist contract and remain contracted if this combination be required to take part in the superadded movement of extension of the wrist. Now if the movement of extension of the fingers is not made to the full extent and the superadded movement of extension of the wrist becomes the predominant one, the flexors of the wrist cease acting as soon as pressure is applied to the dorsum of the first phalanges, although the extensor communis digitorum is taking part in the movement and its tendons can be seen to stand out. I think that these experiments show that if the movement of extending the wrist be performed with the fingers extended, the extensors of the fingers have to do all the work themselves and against the contraction of the flexores carpi, until the amount of work done amounts, as in my own case, to three or four pounds, when the extensores carpi will join in and help them.

Now to apply this to what we find in lead paralysis In paralysis of the extensors of the fingers due to lead, if the movement of extension of the wrist be started by that of attempting to extend the fingers, the extensores digitorum being paralysed cannot move at all and so cannot possibly reach the amount of three pounds which, as we have seen, is required for them to attain before the extensores carpi will come in and help them. The important point is that the patient has no power to make the extensors of the carpus contract and the only resulting movement is flexion of the wrist due to the synergic action of the flexores carpi. It rather reminds one of some highly organised establishments where, if one of the servants be incapacitated, it is no one's place to do the work which is consequently left undone.

Following on the results obtained from examining the action taken by the extensors of the fingers in extending the wrist I have examined the movement of flexion of the wrist to see the part taken in that movement by the flexors of the thumb and fingers. I have already mentioned that the flexors of the fingers take part in the flexion of the wrist and they do so very readily. It is also to be noted than when the flexores digitorum act as flexors of the wrist the synergic action of the extensores carpi does not occur. When, however, we cause the fingers and thumb to contract powerfully, as in grasping, and while this is occurring we flex the wrist, we get an entirely different condition.

Here we have taking part in the movement of grasping the flexors of the thumb and fingers and also the synergic action of the extensors of the wrist and the question is, what will happen if we now flex the wrist? Will the movement be done by the flexors of the fingers or will the flexors of the wrist come and help and, lastly, will the extensors of the wrist relax? It will be observed that if this movement be attempted while a strong grasp is maintained and also if the flexion of the wrist be made slowly there are a considerable feeling of strain and a certain amount of tremor due to the antagonism between the acting muscles. To determine the three above-mentioned points the following method was used: 1. It was first necessary to insure that the grasp of the hand was being maintained throughout the observation and this was done by means of a dynamometer which was grasped in the hand and the index of which could be watched, for I found that in flexing the wrist against resistance as soon as the grasp was relaxed the flexors of the wrist immediately contracted even in the slightest degree of flexion, and as I have already mentioned the whole experiment depended on the grasp being maintained. 2. The forearm was put in the position midway between supination and pronation and a band was passed round the metacarpal bones and either traction was made horizontally in the direction opposed to flexion of the wrist or flexion was made by the wrist against a fixed point; a spring balance was attached to the band and the amount of traction was read off at which the tendons of the flexors of the wrist were felt contracting and also the amount of traction required to make the tendon of the extensor carpi radialis relax. In my own case I found that the tendon of the palmaris longus could be felt first and when the balance measured three pounds, whereas the tendons of the flexores carpi radialis and ulnaris were not felt till from five to six pounds of traction was made. On the other hand, the tendon of the extensor carpi radialis was not felt to relax till as much as from 14 to 16 pounds' traction had been made. The strained feeling would therefore be due to the antagonism between the extensors of the wrist and the flexors of the wrist. These experiments would seem to show that the combination between the extensores digitorum and flexores carpi and also between the flexores digitorum and extensores carpi is so strong that the muscles which flex and extend the wrist will oppose each other rather than sever their connexion with the finger muscles when the wrist is being extended or flexed in conjunction with extending the fingers or flexing the fingers and thumb.

While discussing the question of the action of the extensors of the wrist with the flexors of the fingers it will be advisable to say a few words about the nature of this combination. Duchenne calls attention to the definite association between the above-mentioned muscles, as well as that between the extensors of the fingers and flexors of the wrist, and that between the extensor ossis metacarpi pollicis and the extensor carpi ulnaris. He speaks[15] of the "moderating synergy," and he writes "that the synergic contraction of the flexors of the hand on the forearm is inseparable from the muscular function which ought to produce voluntary extension of the first digital phalanges. To place the common and special extensors of the fingers in the greatest elongation in order to augment their dynamical power: such is the useful end of this instinctive combination of the flexors of the hand during extension of the fingers." He refers to the over-extension of the wrist which occurs in extending the fingers when the flexors of the wrist are paralysed and the explanation which he gives is that "the common extensors of the fingers being up to a certain point at the same time extensors of the hand on the arm their contraction renders necessary the moderating synergy of the flexors of the wrist." One of the earliest mentions that I can find about a muscle passing over two or more joints is that of William Cowper[16] who in his Anatomy reproduces Bidloo's splendid anatomical plates. He gives various reasons why a muscle passes over two or more joints, but he does not mention that other muscles are brought into the movement. John Hunter[17] in his second Croonian lecture delivered before the Royal Society in 1777 was as far as I can ascertain the first to enunciate the doctrine of synergic muscles. He says: "Muscles often go over two, three, or four joints and only move the third and fourth, as the flexors of the last joints of the fingers; but to prevent th[illegible] action the exter[illegible]iged to interfere [illegible]s really the use of [illegible]xors of the wrist [illegible] in the greatest [illegible]namical power so that when the wrist is flexed to a right angle the grasp has about one-half the strength that it has when the hand is in a line with the forearm, yet that, I think, is not their object. For if the wrist be extended passively as far as it will go and if then the fingers be actively extended the flexor carpi ulnaris will still be felt to contract without remedying the position of the wrist-joint even though the extensors of the fingers are working at a great disadvantage. If the function of the flexors of the carpus was to put the *extensors of the fingers in the most advantageous* position they would flex the wrist and bring the hand into position in a line with the forearm. Their function appears to be to fix the wrist in whatever position it happens to be, so that the fingers will have a secure basis to work upon. Following the opinion stated above by John Hunter I think the condition may be stated thus: When a muscle by passing over two or more joints has two or more different actions, then, if only one of these actions is required, other muscles are brought into the movement whose actions are antagonistic to those of the muscles which are not required. In the above quoted case the extensors of the fingers by passing over the wrist are extensors of the wrist as well as extensors of the fingers, and as extension of the wrist is not required the antagonists to this action—viz., the flexors of the wrist—are brought into the movement and the resultant movement is extension of the fingers without extension of the wrist. This rule applies as far as I have been able to observe throughout the muscular system. These muscles which are brought into action to neutralise an action which is not required I should propose to call "synergic muscles"—a term used by Duchenne.

LECTURE II.

Delivered on June 11th.

MR. PRESIDENT AND GENTLEMEN,—The next movements that we have to consider are those of the *radio-ulnar articulations*, pronation and supination. The muscles producing pronation are the pronator teres and pronator quadratus and if the resistance to the movement be applied to the hand, as it usually is, the flexor carpi radialis and palmaris longus contract. The pronator quadratus cannot be felt contracting, but it is one of the muscles the action of which must be inferred from its position. Supination is performed by the supinator brevis, biceps, and when the resistance is applied to the hand by the extensor carpi radialis longior and brevior and by the extensors of the thumb. The strongest supinator is the biceps and its action as such was described by Winslow.[18]

In the above list I have omitted the supinator longus, or as it is now called the brachio-radialis. This muscle has had a very chequered career at the hands of anatomists. According to Winslow it "was believed to be concerned only with supination till Mr. Heister observed that it was a flexor of the elbow-joint," and he adds, "before it can act as a supinator the hand must be in the greatest degree of pronation, and even then it can do little more than bring the radius back to its natural position." According to Duchenne[19] the supinator longus flexes and pronates the forearm if it is previously *completely supinated into the mid-position* of pronation and supination and its denomination of long supinator is inexact since the muscle exercises a contrary action. In the anatomical text-books at the present time the teaching is that the supinator longus pronates when the forearm is fully supinated and supinates when the forearm is fully pronated. In the midst of so much conflicting evidence it seems to me that the only way to settle the question is to go directly to natu[illegible] in the living body. Ten[illegible] observation on this musc[illegible] while it took an active part in flexing the forearm, no action in it [illegible] pronation and supina[illegible] extreme pronation and [illegible]re is some slight action [illegible] a point which anyone [illegible] pronating the forearm against resistance, taking care that no flexion of the forearm occurs. I think it will be found that no contraction of the supinator longus will be seen except perhaps in strong pronation, but the moment that the slightest flexion is made the muscle instantly stands out in strong outline. I therefore conclude that the supinator longus, or the brachio-radialis as it would be better to call it, does not take part in supination and only in strong movements of pronation.

It is interesting to note that Duchenne[21] according to his electrical observations considered "that the biceps could not be put isolatedly into contraction without producing supination at the same time," and he cites a case where a person had lost the use of the brachialis anticus, supinatores *longus et brevis*, and the pronators, but not the biceps, with the result that he could not flex the forearm without supination owing to the atrophy of the pronators and from this he argues that we must conclude that the biceps only supinates during flexion of the forearm and he considers that it ought to be called the flexor supinator. He also seems to hold the opinion from this that simple supination is performed by the supinator brevis and simple pronation by the pronatores teres and quadratus, whereas the biceps, he considers, only takes part in flexion supination and the supinator longus in flexion pronation.[22] But what are the facts of the case? No doubt the biceps is a flexor as well as a supinator and yet if one examines one's biceps when the forearm is being supinated against resistance without flexion of the elbow, and this is a movement which everyone can perform, the biceps is found to be vigorously contracting and it certainly can act without flexion of the elbow. It was while examining this point that it suddenly occurred to me: Why does not the elbow flex in supinating the forearm when the biceps is contracting so strongly? There must be some opposing force to prevent flexion. We have here, in fact, an example of a muscle, the biceps, having two actions, supination and flexion, of which the latter is not required and therefore, according to the rule given in the first lecture, the antagonist to this flexor action must be brought into the movement. The antagonists to the flexors of the elbow are the extensors of the elbow. In other words, it is not possible to have strong pure supination without contraction of the triceps. If, however, while supinating, it be required to flex the elbow, the triceps at once ceases to contract. Further, if the triceps be paralysed the patient cannot supinate without flexing his elbow, because the flexor action of the biceps is not neutralised; and if the biceps be partially paralysed and weaker than the triceps, the elbow is extended during strong supination just as the wrist is over-extended in grasping when the flexors of the fingers are weak. It is also to be noted that apparently it is not the whole triceps which takes part equally in this movement, for of the three heads by which the triceps arises the outer and inner head contract more than the long head arising from the scapula. The probable reason for this is, as we shall see later, that the long head of the triceps is an adductor of the humerus; now the only counteraction required in this movement of supination is extension of the forearm and not adduction of the humerus, therefore the part of the triceps which performs this movement of adduction does not contract so readily. As we shall see later the pronator radii teres is also a flexor of the forearm on the arm as well as a pronator—though Winslow[23] states that it can have no action but pronation—and to neutralise its flexor action there is also contraction of the triceps but to a much less degree than in the case of supination in proportion as the flexor action of the pronator teres is much less than that of the biceps.

[20] On Some Points in the Action of Muscles, Brain, vol. xiv.

[21] Loc. cit., §§ 146, 147.

[22] Loc. cit., p. 142.

The movements of the elbow-joint are flexion and extension; the muscles which take part in flexion are the biceps, brachialis anticus, supinator longus, pronator radii teres, and when the hand is closed there is very slight action in the flexores carpi but none in the extensores carpi. In the above list the brachialis anticus is certainly a pure flexor of the forearm and as the supinator longus does not, according to my observations, take part in the movements of supination I look upon it as a flexor with slight pronator action. We have therefore the supinator longus and the pronator radii teres acting as flexor pronators and the biceps as a flexor supinator. Now, flexion of the forearm can be performed when it is in the position of extreme pronation or supination or in any position intermediate between these two, so that the muscles which pronate and supinate the forearm at the same time that they flex must be in equilibrium, but the opposing muscles are the supinator longus with the pronator radii teres as pronators and the biceps as supinator—muscles so different and unequal in strength that it does not seem possible that the former two can balance the biceps. I can only suggest, though I have not yet come across a case of isolated paralysis of the pronator quadratus, that this muscle may assist the pronator teres and supinator longus in neutralising the supinator action of the biceps in simple flexion of the elbow. The association of flexion or extension of the elbow with pronation or supination produces some interesting combinations; for instance, if while flexing the elbow the forearm be supinated the pronator radii teres, which was acting as a flexor of the elbow, seems to me to cease as soon as the movement of supination is performed, but, on the other hand, the biceps does not cease to act in flexing and pronating at the same time. Now what will be the action of the biceps if during supination the forearm be extended? Will it continue to act by virtue of its position as a supinator or will it cease when it takes part in the movement of extension to which its action of flexion is an antagonist? The answer is that the biceps contracts during the combined movements of extension of the elbow and supination of the forearm and therefore the action of the extensors of the elbow must be stronger than the flexor action of the biceps, otherwise there would be no extension.

What part do the flexors and extensors of the carpus take in the movements of the elbow? According to Duchenne[24] the flexors of the wrist are auxiliaries of the flexors of the elbow and when these are weak the flexor of the wrist are put on the stretch by extending th wrist and can then assist to flex the elbow. My experience is that the action of the flexors and extensor of the carpus is exceedingly slight as flexors of th forearm on the upper arm. In cases which I hav had where the supinator longus was absent and th biceps was very feeble the patients in flexing the elbow firs pronated the forearm, the extensors of the wrist then contracted, hyper-extending the wrist, and finally the elbo very slowly flexed. It was difficult in these cases to sa whether the flexion was performed by the pronator teres an flexores carpi or by the pronator teres and the extensore carpi. William Cowper[25] expressed the opinion that th flexors of the carpus when they "act together, as they d when they bend the wrist, destroy each other's action on th elbow and have little or no effect on it." To ascertain th share taken by the flexors and extensors of the carpus i flexing the elbow I have tested the amount of work done b flexion of the elbow when the flexors of the wrist took par in the movement and when they did not. The trial was mad first with the resisting band over the hand just above th heads of the metacarpal bones so as to include the carpa muscles, and on flexing the elbow the maximum amount c work was found to be about 40 pounds, whereas on placin the band over the lower end of the radius and ulna th amount went up to from 50 to 54 pounds. This increase i due to the shortening of the arm of the lever of the thir power by transferring the weight from the hand to the lowe end of the forearm. To obviate this the resistance band wa applied to the lower end of the forearm with (1) the wris tightly clenched and (2) the wrist lax. In several observations identical figures were given in the two cases in one observation when the wrist muscles were used th force was two pounds more. The proportion of two in 50 is s small that the power of flexing the elbow by the muscle of the carpus is proportionally very slight and is almost negligible quantity. The effect of shortening the arm o the lever is very well shown by putting the resisting ban in the middle of the forearm when the amount of work don goes up to 70 or 80 pounds, as against 50 pounds when th band is over the lower end of the radius, and it is wel exemplified by a person carrying a heavy basket by th handle on the bent arm, putting the handle as near to th elbow as possible.

The extensor carpi radialis longior, which arises from th lower third of the outer condyloid ridge of the humerus, ha been considered to be a flexor of the elbow-joint, but whe the wrist is lax I cannot find that there is any contractio of this muscle when strong flexion of the elbow with th forearm pronated is made against a resistance.

To determine the question of the relative strength of th flexors of the elbow in the various positions of supinatio and pronation of the forearm I have taken the maximum i myself when the forearm was completely pronated, when i was completely supinated, and when in the mid-positio between the two. When fully pronated the amount wa 40 pounds and in the other two 42 pounds, so that, as befor said, in the position of pronation the supinating action o the biceps must be neutralised, as the flexor force is nearl the same in all three positions.

Extension of the elbow, or rather of the bones of th forearm on the humerus, is performed by the triceps an anconeus, and I am unable to find that the extensors of th wrist or fingers take any part in the movement

The movements of the humerus on the scapula are s involved with the movements of the scapula itself tha it will be more convenient to take them together an afterwards those movements of the scapula which ar performed without the participation of the humerus. Th movements of the humerus are best described in term of the planes corresponding to the three dimensions o space—viz, antero-posterior, latero-vertical, and horizontal In the antero-posterior plane the humerus starting fron the hanging position is advanced forwards, flexed as i is also called, to the horizontal line and thence it i elevated to the vertical position; on the return journey th humerus is depressed through 180° to the hanging position and thence it can be carried backwards or retracted. I the latero-vertical plane the humerus can be abducted to the horizontal line and thence to the vertical and on the return journey it is adducted through 180° to the hanging position. In the horizontal plane the humerus is horizontally adducted when it is moved towards the middle line and horizontally abducted when moved away from the middle line to the lateral plane, behind which it is horizontally retracted. Besides the above movements there is rotation in and out. In advancing the humerus the anterior fibres of the deltoid, the clavicular fibres of the pectoralis major, the biceps, and probably the coraco-brachialis, contract and carry the humerus forward, nearly to the horizontal line. This action tends to rotate the scapula with the acromion downwards and to push its inferior angle towards the spinal column, but this is prevented by the contraction of the acromial fibres of the trapezius—which Duchenne showed to be the fibres taking part in this movement and not the clavicular fibres—and it is also prevented, as I consider, by the contraction of the inferior fibres of the trapezius. As shown by Duchenne the deltoid and the other muscles cannot carry the humerus further than the horizontal line. After passing through 45° the serratus magnus comes to their assistance and draws the lower end of the scapula forwards, raises the acromion with the humerus and thus the arm is elevated to the vertical position. Now th[illegible] end of the s[illegible] I have seen c[illegible] this idea. The first case which drew my attention to this point was that of a girl who had wasting of the lower part of the trapezius, below a line drawn horizontally from the spine of the scapula to the vertebral column. The rest of the trapezius acted well and the serratus magnus was not affected, which was well shown by the patient being able to push forward with the advanced arm against resistance. On telling the patient to advance the arm slowly I observed that the first action on the scapula was to rotate it so that the inferior angle moved half an inch towards the vertebral column and the posterior border of the scapula projected like a wing; this projection reached its maximum when the humerus was advanced through about 45°. Then the serratus magnus contracted and as it drew the lower end of the scapula forwards the deformity diminished and finally disappeared. The explanation that I would offer for this occurrence, which does not happen with normal muscles, is that though the serratus magnus is mechanically in the position to fix the scapula and to prevent its lower angle from being rotated towards the vertebral column, it is not its function, when the movement is one of advancing the shoulder, to act on the scapula until the humerus has been moved by the deltoid through about 45°. The inferior part of the trapezius apparently is the proper muscle to fix the scapula in advancing the humerus and when these inferior fibres are paralysed the serratus will not step into the breach, so to say, and do the work for the trapezius, which consequently is not done at all. I think that this is another instance of what I described in the previous lecture in the case of paralysis of the extensors of the fingers due to lead poisoning and the inability of the extensors of the wrist to help the extensors of the fingers until the latter experience a given degree of resistance. I consider that in a movement such as advancing of the humerus certain muscles are told off to come into action at a certain period of the movement and not before. [A case (under the care of Dr. Ormerod) with paralysis of the inferior fibres of the trapezius was shown to illustrate this movement of the scapula.]

---

[23] Loc. cit., § 889.

[24] Loc. cit., § 167.

[25] Loc. cit., p. xxvii.

I have lately had the opportunity of examining a case under the care of my colleague, Dr. James Collier, where the whole trapezius had wasted and practically disappeared from a lesion of the spinal accessory nerve in the neck, with the result that at rest the scapula was half an inch lower than on the other side and the acromion was rotated downwards and forwards so that the base of the scapular spine was two inches further away and the inferior angle was half an inch further away from the vertebral column than on the other side. On making this patient abduct or advance the humerus it was seen that the inferior angle moved inwards or backwards for half an inch and when the movement of the arm was resisted for as much as an inch, until the humerus had moved through an angle of 45°, when the inferior angle of the scapula was drawn forwards by the serratus magnus, the deformity disappeared, and the humerus was powerfully carried [illegible] to the vertical position. In this case, as the trapezius was the only muscle paralysed, the deformity and backward movement of the scapula must be due to its absence and the only conclusion that we can draw is that although the serratus magnus is in the anatomical position to be able to act, and is generally supposed[26] to fix the scapula, the will has apparently no power to make it act before its appointed time and to take the place of the paralysed trapezius. Whether it would be possible to educate the serratus and by practice to induce it to contract sooner I am not in a position to state, but if the condition may be taken as the same as that of paralysis of the extensors of the fingers in lead paralysis I should think it doubtful.

What determines the period at which the serratus begins to act it is difficult to say, but it seems to have some relation [illegible] th the scapula or to [illegible] and the tension it produces on the scapula. Normally in advancing the arm the scapula hardly moves at all till the humerus makes an angle of about 45° and then the inferior angle begins to move outwards by the commencing action of the serratus and when the humerus is horizontal the angle with the scapula remains constant and the elevation of the humerus to the vertical position is completed by the serratus. If, however, the deltoid is paralysed or the shoulder is fixed the serratus begins to act at once and the scapula moves outwards at once; so much so that this movement of the scapula is a diagnostic sign of one of the two above conditions. Now it is quite easy to imitate normally this movement by rotating the inferior angle of the scapula forwards and the acromion upwards without first moving the humerus, but in none of these conditions is the movement imitated by the action of the deltoid and there is no displacement of the inferior angle of the scapula backwards or towards the spine.

Another point of interest, occurring incidentally, is that the projection or winging of the scapula may be caused by paralysis of the trapezius and especially of its lower fibres, as well as by the well-known paralysis of the serratus magnus. The difference between the two conditions is that the deformity due to the absence of the trapezius is less than that of the serratus, the scapula projecting only half an inch, and that it reaches its maximum when the humerus is advanced through 45°, after which the deformity diminishes and disappears when the humerus is horizontal; moreover, the humerus can be elevated to the vertical position. With paralysis of the serratus magnus the deformity increases as the arm is advanced and reaches its maximum when the humerus is horizontal, beyond which level there is no muscular power to raise it. The diagnosis of paralysis of the serratus is also confirmed by the ease with which the scapula can be displaced backward by pushing against the advanced arm, which is not the case with the trapezius paralysis.

The action of the upper fibres of the pectoralis major in advancing the arm is important and was described by Winslow.[27] It is an action which does not appear in some people until the arm is advanced in a plane nearer to the middle line than the antero-posterior plane. The description just given of advancing the humerus applies equally well to the movement of abducting the humerus, with the exception that the middle part of the deltoid and the supraspinatus abduct the humerus, and the pectoralis major does not act, but the same conditions are met with in regard to the movements of the scapula and its relation to the [illegible] in the movement of advancing the [illegible]duction of the shoulder are [illegible] the erectores spinæ, a subject [illegible] the muscles of the trunk are considered. Depression of the humerus in the antero-posterior plane from the vertical position above the head through 180° is performed by the sternal fibres of the pectoralis major, the pectoralis minor, the latissimus dorsi, [illegible] the te[illegible] the lo[illegible] laris. [illegible] are not from my observations depressors of the humerus and I cannot agree with Duchenne[28] that these fibres are at the same time depressors and elevators of the humerus according to the position of the limb—i.e., depressors only from the vertical to the horizontal line—and that they are, as Duchenne gracefully describes, the agent used equally by the enemy to strike with a sword or by the priest to bless the faithful. I cannot discover that the upper fibres contract at all in forcibly depressing the humerus *in any position* and I was interested to find, what I was not aware of, that Winslow[29] states that the superior fibres serve chiefly to raise the arm forward. Duchenne's opinion was evidently founded on the fact that if the humerus be elevated vertically and the superior fibres be stimulated electrically they will depress the humerus to the horizontal line, but according to my observations they do not contract voluntarily to depress the humerus, and although they are in the anatomical position to depress the humerus they are not included in the group of muscles told off to perform this movement.

---

[26] See Duchenne, loc. cit., p. 115.

[27] Loc. cit., [illegible]

[28] [illegible]

Of the other muscles depressing the humerus I would refer to the long head of the triceps. Now, as this muscle cannot contract without extending the elbow there is also, if only pure adduction be required, slight synergic action on the part of the biceps and supinator longus to neutralise the extensor action of the triceps. This action of the long head of the triceps is very well seen in cases—of which I have one under my care at the present time at the National Hospital for the Paralysed and Epileptic—where the triceps is unaffected, while the flexors of the elbow are paralysed. Here every time the patient depresses or adducts the humerus the elbow is extended by the unopposed long head of the triceps.

Retraction of the hanging humerus posteriorly to the vertical line is performed in addition to the latissimus dorsi and teres muscles by the posterior half of the deltoid. The pectoralis minor takes part in the movement but not, I believe, the pectoralis major, so this movement is a means of separating the action of these two muscles.

Adduction of the humerus is performed by the same muscles as take part in depressing the humerus, with the addition that both parts of the pectoralis major, and also the posterior fibres of the deltoid, act as adductors, as Winslow[30] pointed out. According to Duchenne[31] "electrical experiment shows that the posterior third of the deltoid acts synergically with the other fibres of the same muscle to elevate the humerus through an angle of 45°, but above this point the posterior fibres become depressors of the humerus and antagonists to the other fibres until it has descended to that point of elevation which results from the contraction of the posterior bundle." "This," he says, "justifies the opinion of Bichat,[32] contested by many anatomists, that the deltoid can be at the same time both elevator and depressor of the humerus." My observations would make me join the ranks of the contestors of this opinion, as I cannot find that the posterior fibres of the deltoid take any part in elevation of the humerus and they are in my opinion adductors. On this question I would again like to point out that because a muscle can produce two opposite movements when stimulated by faradisation we cannot be certain from this that this muscle performs these two opposite movements when acted on by the will. We have first to prove that the muscle is actually contracting in each of these opposite conditions, for it does not follow that because a muscle is in the anatomical position to take part in a movement therefore it *must* do so.

In both movements of depressing the humerus and adducting it the scapula has to be fixed by the rhomboids and the lowest fibres of the trapezius, so that when the former are absent the inferior angle of the scapula is drawn into the axilla by the teres muscles, as was first pointed out by Erb, and when the lowest fibres of the trapezius are absent the scapula is lifted upwards by the rhomboid and the teres muscles. The contraction of the rhomboid is, however, stronger than that of the trapezius and in some cases the latter appears not to act in adduction. Conversely, when the adductors are weak and the rhomboid is normal it carries the inferior angle of the scapula to the spine in adducting the humerus. The pectoralis minor also fixes the scapula in depressing the humerus, and when it is absent, as I have lately seen in a case, the scapula is elevated and the coracoid process projects under the skin

In depression and in adduction of the humerus from the horizontal line there is contraction of the abdominal muscles, as was pointed out by Winslow,[33] and especially of the rectus abdominis and obliquus externus, which fix the ribs and prevents them being drawn up by the pectoralis major. In depression I have found that the recti of both sides act, but those of the same side much more than those of the opposite side, while in adduction the rectus of the same side only contracts but in addition the erector spinæ of the same side takes part The question is whether the abdominal muscles are essential for the performance of the movements or whether it is possible to perform them without coöperation of these muscles. I have therefore ascertained the amount of work that is required to be done before the rectus abdominis contracts in the movement of depressing or adducting the upper limb from the horizontal line. I find that the amount is exceedingly small and that in the erect position, with the arm in the horizontal position, the rectus abdominis could be felt to contract when the scale only registered from 4 to 7 pounds, and as this includes the dead weight of the arm, which was found to be 2½ pounds, the actual work done by the muscles was from 1½ to 4½ pounds, and this small amount was sufficient to bring in the fixing action of the rectus abdominis. The smallness of this amount is further shown when compared with the maximum amount of force which can be produced by this movement. In my case it was 30 pounds, so that the earliest contraction of the rectus abdominis occurred when only about one-fifteenth of the maximum strength had been used. It therefore occurs not at the end of a strong movement, but so early that the movement can hardly take place without it. As this action of the rectus takes place equally well in standing, sitting, or lying down its participation is not necessary for maintaining a certain position and therefore I think it must be included in the list of muscles which are essential for the movement of depression and adduction of the humerus.

The movement of horizontal adduction which takes place when the advanced humerus is drawn horizontally to the median line is carried out by the anterior fibres of the deltoid, the coraco-brachialis, and by the pectoralis major; where there is no resistance by the upper fibres only, but where an obstacle is to be overcome both parts of this muscle act.

I would here say a few words about the pectoralis major, one of the most interesting muscles of the body. The pectoralis major is a muscle consisting of two parts, clavicular and costo-sternal, which can either act in unison or in antagonism. The best way to bring out the actions of the two parts working together is passively to advance the upper arm to the horizontal line and then to tell the patient to carry his hand towards the middle line against resistance. If he then raises his hand upwards against resistance the upper fibres alone contract and if he depresses his hand the lower fibres alone contract. In fact, as Winslow said, the pectoralis major may be looked upon as two distinct muscles, and I have published[34] cases of complete absence of the lower fibres due to infantile paralysis with perfect preservation of the upper fibres. Associated with the loss of the lower pectoral fibres there was complete paralysis of the latissimus dorsi and triceps. In horizontal abduction the different fibres of the middle part of the deltoid successively come into action from before back until the posterior fibres act, together with the latissimus dorsi, teres muscles and subscapularis. Associated with horizontal abduction of the humerus is the fixation of the scapula by the trapezius in which all but the clavicular and acromial fibres take part. This is the best movement to bring out the trapezius and particularly the middle part which it is often very difficult to make out For this purpose the upper limb is put in the horizontally advanced position parallel to the middle line and it is then passively pushed backwards so as to make the posterior edge of the scapula visible. If now the patient be directed to abduct the humerus horizontally against resistance, the fibres of the trapezius and especially those inserted into the spine of the scapula are well seen against the sharp edge of the posterior border of the scapula and they have a direction almost horizontal and not so oblique downwards and outwards as the fibres of the rhomboideus minor, with which they might be confounded.

Of the rotators of the humerus the rotators in are the pectoralis major, both parts, deltoid (anterior fibres), teres major, latissimus dorsi, and probably the subscapularis. I have nothing to add to the muscles usually *included as rotators out—viz*, teres minor, infraspinatus, and deltoid (posterior fibres)—except to point out that in *rotation* in when the humerus is horizontal, the rhomboid chiefly acts to fix the scapula and in rotation out the lowest fibres of the trapezius perform this function. Consequently in paralysis of the trapezius there is great displacement of the scapula in rotation out of the humerus but not with rotation in.

The scapula has also movements which are independent of those of the humerus—viz., elevation, depression, advancing, retraction, and rotation with the acromion upwards which has already been described. Elevation is performed by the trapezius and especially by the acromial fibres, though the clavicular do also contract in some patients though apparently not in all, and by the levator anguli scapulæ. According to Duchenne[35] the inferior part of the serratus magnus is an elevator of the shoulder as shown by electrical faradisation, and upon being stimulated the serratus first rotates the scapula with the acromion upwards and then elevates it. Nevertheless, Duchenne states that when he made a person elevate the shoulder and he applied strong resistance to its point, he found that the trapezius, rhomboid, and the upper part of the pectoralis major alone contracted but not the serratus magnus. Yet as soon as the patient raised his arm the muscle contracted at once. He explains that the reason why the serratus magnus does not act is probably because its contraction would interfere with respiration in keeping elevated the ribs on which it takes its origin. I venture to think that the will has not the power to leave a muscle out of a group if it is included in it, even if it interferes with respiration, and that the explanation is rather to be found in the fact that the serratus magnus is not an elevator of the shoulder and also that the electrical results are not to be relied upon unless they are corroborated by voluntary movements. I also think that Duchenne is not distinguishing between the two different movements of (1) elevation of the acromion where the scapula is rotated by the serratus magnus and (2) elevation of the whole scapula as in shrugging the shoulders where the serratus magnus does not act.

I have nothing special to remark about the other movements of the scapula except that the levator anguli scapulæ sometimes takes part with the serratus magnus in advancing the scapula and perhaps it counteracts the rotation of the scapula, with the acromion upwards, by the serratus magnus.

With regard to movements of the spinal column, the chief movements of the lumbar spine are flexion and extension, lateral flexion to either side, and rotation to either side. The flexors of the spine are best tested when the person is lying down. The chief of them are the recti abdominis with the pyramidales and also the external obliques, but whether the internal obliques also take part I have had no means of ascertaining. In testing the action of the recti abdominis the person lies flat on his back and crosses the arms on the chest and the thighs are then fixed by passive pressure. It is then often sufficient for the person to bend the head forwards for the recti to tighten up sufficiently to be felt. The complete movement of sitting up from the recumbent position consists of two stag[illegible] to the pubes by [illegible] and then the pe[illegible] the psoas and iliacus and other flexor muscles. It is often important to know, especially in cases of tumour of the spinal cord, if any part of the recti abdominis are paralysed as they are long muscles which are supplied from the sixth to the twelfth dorsal nerves. I observed some years back a symptom which enables the observer to tell if there is any weakness of the upper or lower parts of the recti. This symptom is the movement of the umbilicus. In health in the movement of sitting up the umbilicus does not alter its position, but if from a lesion of the lower part of the cord or its nerves the part of the recti below the umbilicus is paralysed the normal upper part of the recti draws up the umbilicus sometimes to the extent of an inch. As the abdominal wall at the level of the umbilicus is supplied by the tenth dorsal root any marked elevation of the umbilicus in the act of sitting up would show a lesion between the tenth and twelfth dorsal segments of the cord or the roots coming off from them. In the case where I first observed this symptom there was a malignant growth involving the cord at the level of the eleventh and [illegible] ly and the [illegible] Ormerod [illegible] I have no doubt, to weakness of the part of the recti situated above the umbilicus. In cases where the recti abdominis are completely paralysed, as in one case of myopathy which I have seen, the patient cannot approximate the ensiform cartilage to the pubes, and he has first to fix the spine by the erectores spinæ and then to flex the pelvis on the femora and to draw the spine with the abdomen convex forwards by the psoas and iliacus, the flexor muscles of the hips.

The extensors of the spine are the erectores spinæ which can be well felt at their origin on either side of the lumbar spine but whose divisions into ilio-costalis and longissimus dorsi I do not think that it is possible to make out. The action of these muscles can best be made out by making a person, while lying down prone on a bed, lift up the neck and the upper part of the trunk when the muscles can be felt and seen on either side of the lumbar spinal column, or by making the patient extend the spine from the position of bending forwards either in the standing or sitting position.

In connexion with the actions of the flexors and extensors of the lumbar spine are the muscular movements which regulate and maintain the erect posture. In the erect posture—i.e., standing with the feet together in the position of attention—the muscles have to be continually counteracting the influence of gravity, and although when work is being done, as in pushing forwards against an obstacle or as in keeping a door shut, the flexors of the spine act, yet when a person bends forward from the erect position without having to overcome an obstacle it is not the flexors of the spine which act but the extensors, and conversely in extending the spine, as in leaning backwards from the erect position, it is not the extensors of the spine which act but the flexors. This condition has been, I venture to submit, much overlooked in books of general anatomy and also in special books on anatomy for artists. In the one by the late Mr. John Marshall[36] I cannot find any allusion to this point and in a recent similar work[37] the following passages occur on p. 37: "This bulging of the muscles on either side is particularly noticeable when these muscles (erectores spinæ) are in a powerful state of contraction as when a person …… is bending backwards." And again, on p. 121: "If the figure be bent backwards the median furrow is deepened and the erectores spinæ are rendered more prominent owing to the fact that they are now in a powerful state of contraction." If in the above description the movement of bending backwards starts from the erect posture and is not made against resistance I should not be able to agree with it. Merkel[38] also states that in bending forwards the groove in the middle of the back disappears and the vertebral spines become visible and the back becomes smooth and round; [illegible] back muscles of the bent side form a stronger projecting swelling than those on the stretched side. On the other hand, according to the late Mr. W. Adams,[39] the muscles of the spine are in a state of least action when the spinal column is in the erect position. Instead, therefore, of the muscles of the spine in this position being in a state of active tension it is more correct to describe them as in a state of vigilant repose; as soon as the equilibrium is disturbed and the body is inclined to one side the spinal muscles on the convexity of the curve are put on the stretch. Richer[40] also states that on bending forwards the extensors come into action and on bending backwards the flexors of the spine, so that the action is somewhat of a paradox.

But we must go further back to find similar opinions expressed by Winslow,[41] who stated that "the musculi recti serve to support the trunk of the body when inclined backwards . . . for when we stand straight they have no hand in bending the body forward, except we be striving to overcome some resistance." And going further back still we find that Galen[42] in describing his fourth movement of muscles refers to the contraction of a muscle where there is no movement as in the case of maintaining the advanced arm in that position against gravity, so that he evidently recognised that the behaviour of a muscle is different according to whether gravity has to be overcome or not.

[42] Loc. cit., Part VII., Book 2, p. 329.

I should certainly agree with the opinion expressed above by Mr. Adams that in the erect position there is a state of least action of the muscles as very little action is to be felt in the erectores spinæ or in the recti abdominis, but by producing a forward movement of the trunk, as by bending the head forward so as to displace the centre of gravity, the erectores spinæ instantly contract and prevent the trunk from moving further in the direction of flexion, whilst the flexors of the recti abdominis relax. In the same way by extending the head backwards the centre of gravity is displaced backwards and the recti abdominis contract and check any further movement in a backward direction, whilst the erectores spinæ are relaxed. But if it be desired to bend the trunk gradually forward the contracted erectores gradually relax and let out the weight of the trunk in the same way as a heavy weight is slowly lowered to the ground by a crane. This action of these muscles can best be illustrated by the upper limb. If when the upper limb is in the horizontal position the forearm be slowly flexed on the upper arm in the vertical plane the flexors of the elbow contract until the forearm is just past the vertical line, when they cease to act and become quite flaccid while the triceps then contracts and lets the forearm gently flex on the upper arm. Conversely, if in that position the forearm be slowly extended the triceps contracts until just past the vertical line, when it ceases and then the biceps and the other flexors contract and let the forearm be gradually extended. So that in flexing the forearm in the horizontal position the first half of the movement against gravity is done by the flexors and the second half with gravity by the extensors. This applies to all the muscles of the body and it may be expressed thus: In every slow movement which is made in the direction of gravity the muscles which act in the direction of the movement are relaxed while their antagonists contract and support the part and if the movement is continued they gradually relax to their full extent.

The contraction of the erectores spinæ when the body falls forward occurs automatically and apparently without any effort of the will and it can be demonstrated by leaning forwards, supporting the weight of the body on one hand. On suddenly taking the supporting hand away the body falls forward and the erectores spinæ instantly contract. The contraction is an instinctive preservative action performed automatically and it takes place unless a voluntary effort is made to inhibit the contraction, when it can be prevented from acting.

In lateral flexion to one side where an obstacle has to be overcome the rectus abdominis and erector spinæ of that side can be felt to contract together with the external oblique and probably the quadratus lumborum, but in inclining the trunk to one side in the direction of gravity where no obstacle has to be overcome the muscles of that side are relaxed and the muscles on the opposite side—the antagonists—contract, just in the same manner as the erectores spinæ contract in flexing the spine forwards.

In rotation of the spine to the right the left external oblique acts, but neither the erector spinæ nor the rectus abdominis can be felt to contract, but whether the internal oblique of the same side (right) contracts it is difficult to say.

While speaking about the movements of advancing or abducting the humerus it was stated that these were attended by contraction of the erector spinæ. This is a point to which attention has been directed by Dr. J. Hughlings Jackson.[43] When a person stands erect so that there is no contraction of the erectores spinæ and then advances one upper limb with or without a weight in the hand to the horizontal line both erectores spinæ contract, and if the advanced arm be slowly carried outwards through an angle of about 45° the erector spinæ on the same side as the advanced arm ceases to contract and on the arm being carried through another 45° the rectus abdominis of the opposite side will be felt to take part in the movement. The question arises whether this contraction of the erectores spinæ is an essential part of the movement of advancing the shoulder in the same way as the right abdominal muscles take part in depressing or adducting the humerus—i.e., whether it is possible to advance the humerus without bringing the back muscles into action. I think the matter can be proved in the following way:—If when the arm is advanced and the erectores spinæ are felt contracting the spine be extended the erectors will be felt to relax when the weight of the trunk behind the centre of gravity just balances the weight of the advanced arm in front, and if now the arm be dropped and then advanced again no fresh contraction of the erectores will be felt. I think that this shows that the contraction of the erectores is not an essential part of the movement of advancing the humerus, as it does not always occur but is of the nature of a postural contraction and only takes place to prevent the equilibrium of the trunk from being disturbed.

This point, whether the erector spinæ muscle of, say, the left side is an essential component of the movement of abducting the right arm, is interesting in relation to hemiplegia. In right hemiplegia where a patient has lost the power of abducting the right arm the question arises as to whether he has any paralysis of the left erector spinæ which, as we have seen, acts when the right arm is abducted. If the action of the erector spinæ were an essential component of this movement of the arm one would expect that when the movement of the arm was paralysed all the components of this movement would also be paralysed, including the erector spinæ, but if the action of the erector spinæ were not an essential component but only acted to preserve the equilibrium of the spine then we should not expect it to be paralysed. I have not examined a sufficient number of cases to say whether the left erector spinæ is paralysed or weakened in right hemiplegia, but Dr. Hughlings Jackson[44] has expressed the opinion that in some cases of hemiplegia the erector spinæ on the side opposite to the paralysis is weaker than on the other side—i.e., in right hemiplegia the left erector spinæ is the weaker—and that the muscle is probably supplied by the direct (ventral) pyramidal tract.

INTUBATION IN CASES OF DIPHTHERITIC LARYNGITIS.

BY H. A. T. FAIRBANK, M.B., B.S. LOND., F.R.C.S. ENG.,
LATE RESIDENT MEDICAL SUPERINTENDENT OF THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE following remarks are based upon an experience of 33 cases of diphtheria of the larynx in which intubation was performed admitted to the Hospital for Sick Children, Great Ormond-street, under the care of Dr. A. F. Voelcker, to whom my thanks are due for permission to publish these cases and for his generous assistance. Since the introduction of antitoxin in the treatment of diphtheria statistics of cases of intubation have been almost entirely absent from medical literature in this country. Mr. T. H. Kellock[1] in 1896 published five successful cases and Dr. Conrad Basan[2] in 1901 reported 40 cases, of which only seven were fatal. Dr. Basan's cases seem to have been selected, certain cases being considered unsuitable for treatment by intubation. In the present series of cases nine were fatal—i.e., a percentage mortality of a little over 27. At the Hospital for Sick Children, Great Ormond-street, the practice is to intubate all cases of laryngeal diphtheria in which the signs of obstruction are sufficiently severe to call for immediate relief by operation. Primary tracheotomy is only performed in the few cases in which attempts at intubation prove unsuccessful through inexperience on the part of the operator. An analysis of my fatal cases will show that the list includes more than one hopeless case. Taking Mr. Kellock's, Dr. Basan's, and my own series we have, in all, 78 cases of intubation associated with antitoxin treatment, with a percentage recovery of 76·9. In Allbutt's "System of Medicine"[3] Dr. W. P. Herringham quotes 32 cases of tracheotomy in which antitoxin was also made use of, with a percentage recovery of 81·25; Dr. G. Thornton[4] gives 151 cases with a recovery rate of 67·6 per cent.; and Professor E. Roux[5] mentions 121 cases with a percentage recovery of 62·8. If one may judge from such small numbers intubation would seem to give results as good as, if not better than, those of tracheotomy, and this without any wound in the neck being made. Many writers on this subject have stated that the greater the experience of the operator the better will be his results; and this is certainly my own experience, as the last 15 of my patients recovered. It has been stated that intubation should be performed before tracheotomy becomes justifiable. The two operations might almost be reversed in this statement. Intubation can be performed so rapidly and without an anæsthetic that it can safely be postponed till an operation of some sort becomes imperative. In cases of laryngeal obstruction complicated by pneumonia when there is some difficulty in determining the part played by the two affections in the production of the dyspnœa intubation possesses obvious advantages over tracheotomy.

Operation.—The operation of intubation has been described as easy and so it is after a little practice. Experience must be gained in the living subject, practice on the cadaver being of limited value only. In a case with marked œdema glottidis, when the tip of the tube has to be squeezed into the larynx by steady but elastic pressure, the operation is by no means easy to the beginner. At the Hospital for Children, Great Ormond-street, the operation is performed with the child lying in bed, with the object of disturbing as little as possible the absolute rest in the recumbent posture so essential in cases of diphtheria. As a preliminary the child's arms should be encased in a piece of thin cardboard rolled into the form of a tube, lined with wool and fixed with a bandage. This simple splint, which should extend from the axilla to a point just above the wrist, effectually prevents the child from reaching the mouth and pulling out the tube, while allowing toys and books to be handled with ease. After the child has been wrapped in a blanket, with the arms by the sides, the head may be slightly extended over a small pillow placed behind the neck; this enables the mouth to be freely opened, even when the child in his struggles endeavours to bury his chin in his chest. The assistant, standing on the left side of the bed, steadies the gag, which is placed on the left side of the mouth, with the left hand while the right is placed on the child's forehead. Practice enables one to intubate with the mouth, less widely opened than was found necessary in one's early cases. The opening of the gag often causes an increase of the dyspnœa and, according to Dr. G. Hunter Mackenzie,[6] may even cause death. Dr. Basan in his interesting paper mentions a case in which the opening of the gag led to the immediate performance of tracheotomy which failed to save the child. The gag should always be closed or removed between the attempts to introduce the tube. The tube, previously sterilised, should be warmed by dipping it in [illegible] hen smeared with white vaseline [illegible] The method of introducing the [illegible] acting as a guide is described [illegible] diseases of the throat and need [illegible] perienced hands the operation is practically free from danger, though death may occur from syncope, as the following unfortunate case shows.

CASE 1.—A girl, aged three years, was admitted with considerable dyspnœa, stridor, and recession of the lower part of the thorax. Antitoxin was administered and a steam kettle and half-tent were ordered. After a few hours, as no relief was obtained and the child's distress was increasing, it was decided to perform intubation. Two unsuccessful attempts were made by a colleague to introduce the tube. After the first the cyanosis had much increased but the child rapidly recovered on closing the gag. After the second attempt the child was nearly black and stopped breathing. I then introduced the tube and commenced artificial respiration. Air could be heard entering through the tube, but the child rapidly paled and died in spite of subcutaneous injections of strychnine and brandy.

This was not a case of pushing membrane down in front of the tube as air passed freely. The child was unable to stand the brief asphyxia induced by the operation. The diphtherial infection in this case was of a severe type, as was evidenced by two other members of the family, who were affected with the disease about the same time, displaying dangerous [illegible] It [illegible] av[illegible] dis[illegible] by Dr. J. B. Ball[7] and Dr. H. G. Turney.[8] The impediments to intubation are great œdema, excessively thick membrane, and spasm of the glottis. The last gives way, as Dr. Basan says, on inspiration if the tube is kept applied to the glottis. In a case of œdema it may be found useful to slip the tip of the left forefinger behind the arytenoids and so to hold the tube against the posterior surface of the epiglottis to make sure that what little force is used is in the right direction. Dr. W. P. Northrup[9] mentions two difficulties in intubation: (1) the point of the tube entering the ventricle of the larynx, and (2) subglottic stenosis, meaning œdema of the mucous membrane in the region of the cricoid ring. The former should not occur and the latter is easily overcome if a suitable tube has been chosen. The same writer advises care in removing the introducer and obturator. The operator must keep these in the middle line or the obturator will catch and perhaps drag out the tube. The tip of the left forefinger should steady the tube meanwhile and should then push the tube home into the larynx. The epiglottis should be felt to flap over and partially to cover the top of the tube, otherwise the latter will be coughed out immediately. The tubular character of the violent respiration following successful intubation is unmistakeable. In its absence the tube may be pulled at once from the œsophagus into which it has certainly passed.

Size of tube.—The sizes recommended by Dr. O'Dwyer for the different years are rather small and easily coughed out. Some continental surgeons who have visited this hospital have agreed with me in this view. In this series of cases, tubes were used suitable, according to the gauge, for children from six months to two years older than the patients operated upon. The bigger the child the bigger, relatively, should the tube be. The size of the child should be considered rather than his actual age. The male larynx is slightly larger than the female of equal age. Mr. Kellock suggests that the larger the tube used the less the mobility thereof and therefore the smaller the chance of ulceration. Dr. O'Dwyer[10] recommends the use of small tubes in cases with extensive formation of membrane, so that tube and membrane may easily be coughed out together. If too large a tube be used it may irritate the larynx and set up a reflex cough. This apparently happened in a hydrocephalic child whose persistent cough was rapidly relieved by the substitution of a smaller tube. [illegible] out once.

The string.—Although [illegible] commend that the string, which should always be attached to the tube during the operation, should be removed after a few minutes if the child seems to be comfortable and relieved of dyspnœa, I strongly advocate its retention as long as the tube is in the larynx. In all my cases the thread was left attached to the tube, brought out of the corner of the mouth, and fixed to the cheek with a piece of strapping. Two objections are urged against the permanent use of a string. First, that it is a source of worry to the patient; this is, I think, exaggerated; children rapidly get used to it. In only one of my cases was there any trouble from the child biting through the string (*vide* Case 4). Secondly, that it may give rise to a *thread ulcer* on the left half of the epiglottis; Mr. B Pitts[11] and Dr. Turney[12] have reported several cases to prove this. In the four post-mortem examinations on cases in this series, and in post-mortem examinations on some non-diphtheritic cases which I have seen, no such ulcer was present. In all the reported cases of ulceration of the epiglottis due to the thread there has also been severe ulceration elsewhere in the larynx and trachea. It would seem that the former only occurs when the latter, and more serious, ulceration is present and that both result from the low-resisting power of the mucous membrane in certain cases. Abrasion of the epiglottis can, I think, be avoided by careful adjustment of the string on the cheek. Any disadvantage referred to the string on this score is more than compensated by its advantages. The string affords a ready means for removal of the tube by medical man or nurse should it become suddenly blocked by membrane. In the following case the prompt action of the nurse gave the child instant relief and perhaps saved his life.

CASE 2.—A boy, aged two and a half years, was admitted on April 12th, 1902, with faucial and laryngeal diphtheria. Croupy cough began the day before admission. Klebs-Löffler bacilli were present. There was some collapse of the upper lobe of the left lung. He was intubated after the trial of a steam-tent. Dyspnœa was completely relieved. Early on the morning of the 13th the child suddenly got black in the face and stopped breathing. As I could not reach the bedside for some minutes the nurse pulled out the tube which was blocked by a membranous cast of the trachea. The cast was coughed out and the child rapidly regained his colour. The tube was replaced although the child was fairly comfortable. On the 15th the tube was removed; there was no further need for it. The child made an uninterrupted recovery. He was fed by the mouth while the tube was in the larynx, the milk being slightly thickened with arrowroot.

[12] Op. cit. (Cases 3, 6, 7).

In this case the tube was replaced because experience had shown that attempts to dispense with the tube in the first 24 hours are generally useless. The general condition of the child made it desirable that he should be spared the strain of a return of dyspnœa. The chief use of the string is that by it the tube can be removed more easily and rapidly and with less damage to the larynx or trachea than by any other means. The objections to other methods of extraction of the tube will be referred to below.

After-treatment.—As soon as the tube is in place the child should be laid on his side to facilitate the escape of mucus, &c., coughed up. The violent coughing which follows the operation soon gives way to peace and quiet and the child is at last able to sleep. With regard to the important question of feeding most surgeons condemn all feeding by the mouth and make use of the nasal tube or rectal alimentation. Feeding by the mouth is possible in a large number of cases and a trial of this method is to be recommended in all. The early cases in this series were fed by means of the nasal tube, but not being convinced of the necessity for this I endeavoured to feed the rest by the mouth, on the principle that the less the child's mode of life is disturbed the less trouble would there be in dispensing with the tube at a later date. Of 19 cases in which feeding by the mouth was attempted eight were fed thus throughout and all recovered. Of the remaining 11 cases six were fed by the mouth for the most part, only a few nasal feeds being found necessary. All these recovered. Of the other five cases in which nasal feeding was necessary throughout or for the greater part of the time the tube was in use, two died. After intubation a child should be fed by the mouth with food suitable to his age and general condition; in most cases this will be fluid, consisting principally of milk. Many children take this well, if given slowly and carefully, a spoon being used for the younger children. If the child coughs much the milk should be thickened with a little arrowroot. If, in spite of thickening the fluids, attempts at swallowing induce more than an occasional cough feeding by the mouth should be discontinued, the nasal method being substituted for it. Raising the foot of the bed so that the child drinks uphill (Casselberry's position) is unnecessary. The worse the general condition of the child the more difficulty will there be over the feeding. Although there may have been no difficulty in feeding a case while the tube was in place, nasal feeding may have to be resorted to after its removal; this occurred in two or three of my cases. No steam-kettle or tent should be used except when the cough is dry and troublesome, when the effect of the steam may be supplemented by giving expectorants.

An important point is to determine when to take out the tube. In the early stages it should be removed once in every 24 hours for cleaning; this also helps the expulsion of membrane. It is difficult to lay down rules for the removal of the tube, as so much depends on the general condition of the patient. I would suggest the following procedure in a case of average severity. The tube should be removed and replaced at the end of 24 hours. The tube should be removed at the end of a further 12 hours and results awaited. The child is unlikely to get dyspnœa immediately. If the tube has to be replaced it should again be removed after 24 hours. If yet again it has to be replaced it may now be left in for 48 hours; this will often enable the child finally to dispense with the tube. Attempts at discontinuing the use of the tube before 36 hours are almost invariably unsuccessful and result in the operation having to be performed in a hurry. Dr. Northrup[13] says that the older the child is the earlier can the tube be left out. In the cases now under consideration, if those that ended fatally and the two prolonged cases referred to below are excluded, we have 22 cases which ended in recovery. The ages ranged from 11 months to ten years and nine months. The average time that the tube was necessary in 13 cases aged three years and under was six days and nine hours. The time in nine cases over three years of age was four days and five hours. These figures, then, bear out Dr. Northrup's statement. Both the prolonged cases were over three years of age. Mr. Kellock says that the condition of the fauces should guide us in deciding when to discard the tube. In his cases the average time was 27 hours. The longest recorded case is one quoted by Dr. A. Brothers[14] in which the tube was borne for 58 days with interruptions to the end of the twenty-first day. In one of my successful cases the tube was only required for 32 hours. The longest case required the tube till the thirty-fifth day (*vide* Case 4). The longest time the tube was in place without being removed was 79 hours; this case recovered. A slight rise of temperature is not uncommon after the tube is first introduced, but this, as a rule, lasts for a day or two only. This pyrexia may be seen in cases which have been in hospital for several hours prior to the operation and in which, therefore, the temperature as taken before intubation is free from any temporary depression such as may be caused by exposure on the way to the hospital or during washing after admission. In such cases there is no collapse of lung or other obvious cause for the rise of temperature. Rapid and easy insertion of the tube does not seem to prevent this rise of temperature, though roughness may, I think, increase it. I suggest that absorption from the larynx is the cause of this pyrexia. A certain amoun of damage to the inflamed mucous membrane can hardly b avoided.

Extraction of the tube.—Reasons have already been given for leaving the string attached to the tube and thus providing a ready means of withdrawing the latter. The stronges arguments in favour of extraction by the thread are th difficulties and dangers attending other methods. Withou the thread we have to resort to the use of the extractor, o to Bayeux's method of "enucleation," or expression of th tube, unless some form of special tube is in use. Th "enucleation" method was used with success by Dr. Ba who cites a case in which a nurse saved a child by removin the tube in this way. This method is not, in my opinion free from danger to the already irritated trachea. The com monest lesion that is found in fatal cases of intubation is a excoriated surface or ulcer on the anterior wall of th trachea opposite the lower end of the tube. This portion o mucous membrane shows signs of injury after the tube ha been in but a few hours, as a case to be quoted later shows In expressing the tube the thumb is placed on the front o the trachea just below the level of the lower end of the tub and is then pressed upwards and backwards, forcing the tub out in front of it. The force must be transmitted to the tub through the portion of mucous membrane alluded to. Th chances of getting deep ulceration at this spot are thu greatly increased. Mr. Pitts and Dr. W. Brook[15] recor a case of death from gangrene of the lung after intuba tion, the only pathological lesion of the air passage being a healed ulcer on the anterior tracheal wal Enucleation is easily performed with the child lying o his side near the edge of the bed and may be useful the string is bitten through. The extractor is a dangerou weapon, requiring the greatest skill and gentleness in it use if serious damage is to be avoided. Every unsuccessfu attempt at extraction with this instrument must leave th larynx injured by its pointed jaws: the screw which regu lates the separation of the jaws limits but little the damag that may be done. As indicating the distress that may b caused by the manipulations of this instrument I may quot a case mentioned by Dr. Mackenzie[16] in which death occurre during attempts at extraction. Various forms of tube hav been invented with grooves cut in the upper end or flaps rubber to enable them to be removed by a long finger-nail special forceps. As far as I know special tubes have n found favour in this country.

Complications.—Vomiting during or after intubation rare and occurred in only one case of my series. Coughin out the tube is seen but rarely if one of a suitable size h been chosen. This accident was met with in four cases, one of which the tube was expelled twice, on the fir occasion with a definite piece of membrane. Another ca had whooping-cough. In the remaining two cases the tu was rather small: one of these was the hydrocephalic chil already referred to, and the other was Case 4. On int bating, the tube may be blocked at once by membrane

[16] Op. cit. (Case 10).

[illegible]

CASE 3.—The patient was a boy, aged 14 months; he had had whooping-cough recently, though he had not whooped for a week. He had chronic bronchitis. The boy had been worse for the last four days. On admission the child was very emaciated; croupy cough, occasional stridor, and some recession of the chest were present; there were also signs of bronchitis with dulness at the left apex. He was intubated about six hours after admission. Distress immediately increased and no air entered through the tube. The tube was pulled out by the thread and with it a membranous cast of the upper part of the trachea. The tube was replaced with complete relief of the dyspnœa. The child died about 12 hours later, without having had any further trouble with the tube. A necropsy was refused.

If immediate relief be not afforded by intubation or if the child's distress increases the tube should be removed. Membrane may accompany it or be coughed out soon afterwards. Tracheotomy should not be performed in such an emergency until the effect of removal of the tube has been seen. With the thread attached it is a question of a moment's delay only. Membrane may block the tube at any moment during the first few days of intubation. This occurred in four cases of the present series. In one the tube was coughed out and in the other three it was pulled out by the thread. It is advisable to explain to the nurse in charg[illegible] of the t[illegible] loose in[illegible] is a diff[illegible] following three signs of the presence of loose membrane: (1) croupy cough although the tube is in the larynx; (2) flapping sound; and (3) sudden obstruction to the outgoing air, especially during coughing. To these may be added recurrent attacks of urgent dyspnœa of short duration, caused by the loose membrane being jammed in the tube on each occasion. In one of my cases complete blocking of the tube, necessitating its removal, was preceded by two short attacks of dyspnœa. The tube should be pulled out in the hope that the membrane may follow it. Dr. Northrup recommends short tubes of large calibre for use in these cases. The same writer says that a piece of membrane may act as a ball-valve at the lower end of the tube and so give rise to emphysema of the lungs. Dr. O'Dwyer is said, in his first 209 intubations, to have met with three such cases, all of which ended fatally. Mr. Pitts[17] says that Mr. H. Stansfield Collier has also met with cases of rapid distension of the lungs. I have met with one case which, I think, may have been of this nature, although at the time the case was not considered to be one of diphtheria.

Excessive coughing may be associated with the expectoration of thick, tenacious mucus which is expelled through the tube with difficulty and may give rise to definite obstruction. Of more common occurrence is the presence of profuse watery expectoration which keeps the child constantly at work trying to rid himself of the froth; frothy mucus literally pours from the child's mouth. This condition is associated with great restlessness. By laying the child well over on his side and frequently clearing the throat with a swab relief may often be afforded. If this prove of no use the foot of the bed may be raised to help the escape of mucus and a subcutaneous injection of atropine may be given, a little morphia being added if the child be very restless. The following case may be given in detail as an example of the condition just referred to and as presenting other points of interest.

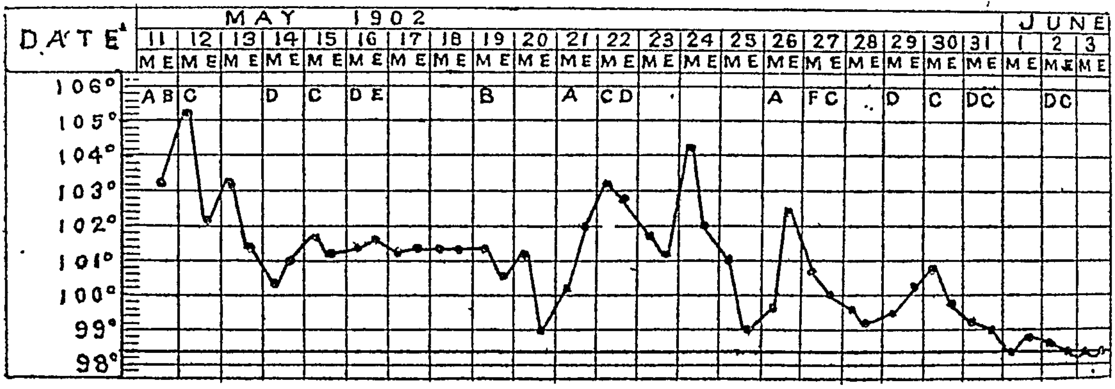
CASE 4.—The patient was a boy, aged five and a half years. There was a vague history of increasing dyspnœa and vomiting for the previous 36 hours. On admission to the Children's Hospital on May 11th, 1902, he was absolutely [illegible] th tonsils. He was intubated [illegible] muco-pus shot into the mouth. (No pus was seen after this.) [illegible] silk thread was bitten through [illegible] be was removed by means of [illegible] and was replaced with fresh silk, but this shared the same fate. Silkworm gut was then tried on the other side of the mouth, but this was divided in a few minutes. Four strands of silk were then used with success. 9000 units of antitoxin were given. The patient was very pale and restless on the night of the 11th. Morphia and atropine [illegible] on the 12th. Rattling in the throat [illegible] quantity of mucus being enorm[illegible] was raised and the injection of atropine was repeated. Klebs-Löffler bacillus was present in cultivations from the throat. The tube was removed, cleansed, and replaced. On the 16th the cough was better. The tube had been removed in the afternoon of the 14th but had to be replaced on the 15th; on the 16th it was removed. On the 18th there was pneumonia at the left base. There was some recession of the lower ribs, apparently due to the condition of lung. On the 19th there was a patch of consolidation at the angle of the right scapula. On the 21st the tube had to be replaced as the recession became much worse. Considerable relief followed. On the 22nd the lungs were better and the tube was removed. On the 26th the tube had to be re-inserted. On the 27th the tube was coughed out. On June 11th the child had worn the tube intermittently since the previous note and still required it in spite of being under the influence of morphia and the bromides which were administered before the tube was removed. The child could do without the tube for periods varying from 50 minutes to four days, after which he suddenly got dyspnœa, requiring immediate intubation. The dyspnœa (? spasm) came on quite suddenly, often on waking; in from one to three minutes he was livid. Inhalations of chloroform were useless; there was no time to get the boy under the influence of the anæsthetic when once the spasm had commenced. There were still some signs of pneumonia at the left base. The tube was removed on the night of the 13th. On the next morning there was some distress which passed off after twice swabbing the larynx with a 5 per cent. solution of cocaine and quieting the boy by talking to him. No further trouble with the breathing occurred. The tube had been in use, with intervals, for 35 days. He eventually made a good recovery.

This case seems to be an example of ulceration of the larynx which recovered under intubation and without tracheotomy being performed. The child was comfortable without the tube from the sixth to the eleventh days and from the thirteenth to the sixteenth (*vide* chart). Some abrasion or ulceration must have been present. During these days the temperature was raised, but the condition of the lungs might account for this. During the last fortnight of the period of intubation the temperature was normal, so that the ulceration was probably slight. The sudden spasm of the glottis in this case indicated the presence of ulceration, though partly depending on the nervous temperament of the child. Fright is often the determining cause in such cases. I have seen a child in whom intubation tubes were being used for chronic stenosis of the larynx get livid because I began to leave the ward immediately after removing his tube instead of staying with him as my custom was. Words are of more use than drugs in these cases; sedatives seem to be of little use, though they should always be tried. As regards the use of cocaine, applied locally in these cases and in those with gradually increasing dyspnœa due to œdema, it is difficult to estimate how much of the improvement should be attributed to the drug. Of two cases in which suprarenal extract was tried with the object of reducing the swelling of the mucous membrane one was relieved. A mixture of cocaine and suprarenal extract might be of more value.

Severe ulceration of the laryngeal mucous membrane is uncommon nowadays. Superficial ulceration is probably present in the cases in which one finds difficulty in discontinuing the use of the tube. The signs of deep ulceration are free bleeding from the larynx during the introduction or removal of the tube, staining of the tube, rapid and repeated appearance of œdema or spasm of the glottis after removal of the tube, tenderness over the thyroid cartilage, and pyrexia. Œdema of the glottis coming on some days after removal of the tube is a certain sign of ulceration. Dr. Turney records a case of œdema coming on 15 days after removal of the tube. At the necropsy ulceration of the larynx was found. If some or all of the above signs are present and yet the child seems to be remarkably well and certainly "holding its own," intubation may still be continued. The general condition of the patient should be our guide when considering the advisability of resorting to tracheotomy. The two long cases already referred to, requiring a tube till the twenty-third and thirty-fifth days respectively, showed some signs of ulceration. Intubation was persisted in because the general condition remained unaltered; the result in both cases justified the treatment. If a child with ulceration of the larynx begins to go downhill tracheotomy should be performed at once The formation of an abscess in front of the larynx or the trachea calls for immediate tracheotomy. Scarlet fever occurring in the course of an intubation case indicates tracheotomy, especially if the child's condition be grave. In my series three secondary tracheotomies were performed, but I am now convinced that in each instance the operation was unnecessary. The first was done because the child was not doing well. The child died with a temperature of 107·8° F. 24 hours after admission. Post mortem broncho-pneumonia was found; there was membrane in the larynx but none in the trachea. In the second case tracheotomy was performed by a colleague in my absence after attempts at re-intubation had proved unsuccessful; recovery followed. The third case was a very severe one, complicated by broncho-pneumonia and anuria. Tracheotomy was performed on the third day on account of the great recession of the lower ribs and sternum, the intubation tube being in place. The coughing set up by the introduction of the tracheotomy tube relieved the child for a short time only; in a few minutes the recession was as bad as ever and was obviously due to the lung condition which proved fatal. No membrane was found in the trachea I believe that tracheotomy is very rarely required after intubation. A large number of secondary tracheotomies have been performed owing to a want of experience on the part of the operator and through a natural fear that the best was not being done for the patient. Mr. Pitts,[18] writing in the pre-antitoxin days, stated that tracheotomy following intubation was very fatal and cited 18 such cases treated at St. Thomas's Hospital, 16 of which proved fatal. Mr. Kellock informs me that out of 14 similar cases at the Hospital for Sick Children, Great Ormond-street, in the years 1890–92 11 patients died. The severity of a case, no doubt, leads to the performance of tracheotomy; still, I believe that in the great majority of cases secondary tracheotomy diminishes the child's prospects of recovery. As to the occurrence of pulmonary complications, signs of which develop after intubation, pneumonia occurred in three cases, two of which ended fatally. In both of these fatal cases death occurred without a tube being in the larynx, the obstruction having been cured. In two other cases bronchitis developed but did not interfere materially with convalescence. Pneumonia, resulting from milk and other food being inhaled through the tube, is regarded by some as common. This does not appear to be the case, though all nourishment is given by the mouth.

---

[17] Brit. Med. Jour., vol. ii., 1893, p. 175.



A, Intubated. B, Nasal feeding. C, Re-intubated. D, Tube removed. F, Fed by mouth. F, Tube coughed out.

A study of the fatal cases is of some interest. Of the nine fatal cases a post-mortem examination was permitted in only four. Of the other five cases, the first was a baby, aged 10 months, admitted for abscesses on both sides of the neck. Six days before death signs of pneumonia appeared. Laryngeal obstruction came on rapidly and intubation was followed by considerable relief, but the child died 24 hours later. The second case has already been mentioned (*vide* Case 3). Broncho-pneumonia developed after whooping-cough and diphtheria ended the case. The child lived for about 12 hours after intubation. Both these cases were really hopeless from the first. In the third case, the patient, aged 20 months, was admitted with nasal, faucial, and laryngeal diphtheria, as well as bronchitis. The child lived till the thirteenth day, the intubation tube being discarded on the eleventh. The heart was considerably dilated and the child gradually sank. The fourth case, a baby, aged 18 months, with severe hydrocephalus, required the tube till the eleventh day, by which time definite signs of pneumonia had made their appearance. The patient died on the fifteenth day with general rigidity and retraction of the head. The remaining case was Case 1, in which the patient died during the operation of intubation. Of the cases in which post-mortem examinations were made the first was admitted with broncho-pneumonia and laryngeal diphtheria and lived one day. Post mortem broncho-pneumonia was found; there was membrane in the larynx and for a short distance below; there was no ulceration; the heart was dilated. In the second case diphtheria occurred at the end of a severe attack of whooping-cough, during which signs of tuberculosis of the lungs appeared. The child died on the day after intubation. Post mortem general tuberculosis was found; there was membrane in the larynx and trachea; a small "intubation ulcer" was found on the anterior tracheal wall opposite the lower end of the tube. The child's serious condition would account for the rapid formation of an ulcer in the trachea. In the third case the patient, aged 17 months, developed pneumonia on the fourth day and lived till the fourteenth, eventually dying from pneumonia; the tube was used till the tenth day. Post mortem pneumonia of the right lung was found; some clear fluid was present in the left pleural cavity; there were no tubercles. In the larynx a deep ulcer with flat injected edges was found in the mid line in front just below the cords. The floor of the ulcer was formed by the crico-thyroid membrane. The usual "intubation ulcer" in the trachea was also present. In the last case the patient died three days after admission from anuria and broncho-pneumonia. Post mortem broncho-pneumonia was found; the mucous membrane of the larynx was distinctly thickened and presented tracts of superficial ulceration; there were no membrane in the larynx or the trachea and no ulceration in the trachea; the tracheotomy wound passed through the usual situation of the "intubation ulcer." Evidences of tubercle were found in the mesenteric glands but not elsewhere. In many of these cases we can, I think, justly conclude that the fatal result could not have been avoided had primary tracheotomy been performed.

In medical literature of the pre-antitoxin days numerous cases of severe ulceration are found; such cases are fortunately rare nowadays. Though no such case is found in this series, I have met with one or two ugly results from intubation in non-diphtheritic cases. The few results given above do not give a correct idea of the damage that may occasionally be done by an intubation tube. Abrasion or ulceration of the mucous membrane can occur very rapidly in debilitated patients. Dr. Turney[19] gives a case of commencing excoriation after eight hours and another of extensive ulceration after 36 hours of intubation. Cases in which the tube slipped through the ulcerated larynx and lodged in the bronchus or the trachea are given by Dr. Turney[20] and Dr. W. W. Ord.[20] The latter diagnosed the accident as the child could phonate, although the tube was supposed to be in the larynx; difficulty in extraction by means of the string confirmed his diagnosis. Stenosis of the larynx, partial or complete, is recorded by Mr. Pitts and Dr. Brook, Dr. Basan, Dr. Chavasse,[22] and Widerhoffer.[23] Dr. Mackenzie gives a case of abscess over the front of the larynx. I have seen a non-diphtheritic case in which an abscess gradually developed over the front of the trachea, although the tube had only been in use for 18 hours. The abscess extended from the cricoid to the thymus gland. Swallowing of the tube has occurred in the practice of several writers. The tube is always passed without trouble. In a case of undiagnosed retro-œsophageal abscess two tubes, of different sizes, were used. At the post-mortem examination two excoriated patches were found on the anterior tracheal wall corresponding to the lower ends of the two tubes. The tubes were both in use for 24 hours. Some excoriation was present in the centre of the posterior surface of the epiglottis. The voice does not seem to be altered for any length of time after intubation. Speech rapidly becomes distinct, though some huskiness may remain for several days or even weeks. In two cases, intubated for three and four days respectively, the voice was still weak three weeks after removal of the tube. The chances of permanently damaging the larynx are small indeed. The boy who required the tube for 35 days (Case 4) recovered the use of his voice completely.

[19] Op. cit. (Cases 4 and 5).

[20] Op. cit. (Case 6).

[21] St. Thomas's Hospital Reports, 1869, p. 65.

In conclusion, I may state that nearly all the above cases were proved to be diphtherial in origin by bacteriological examination and that in each of the cases in which such examination gave negative results definite membrane was discharged from the larynx or trachea. In this country sufficient attention has not been given to intubation. Its employment in a few more hospitals would, I think, eventually lead to its adoption in all.

Harley-street, W.

TWO FATAL CASES OF PARTIAL THYROIDECTOMY,

DEATH RESULTING IN ONE CASE FROM INSUFFICIENCY OF THYROID SECRETION AND IN THE OTHER FROM ITS EXCESSIVE ABSORPTION.

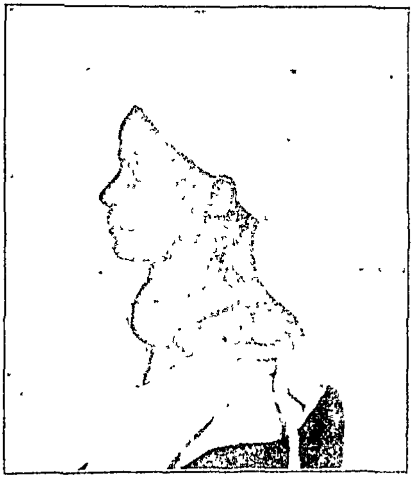
By FRANK COLE MADDEN, M.B., B.S. MELB., F.R.C.S. ENG.,
PROFESSOR OF SURGERY AT THE EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE; SENIOR SURGEON TO THE KASR EL-AINI HOSPITAL, CAIRO.

GOITRE is a very common condition in Egypt and usually has attained such a size before advice is sought that partial removal holds out the only hope of relief from the symptoms which, however, in almost all cases are those of inconvenience from the great size of the tumour and not of injurious pressure upon the trachea, the veins and nerves [illegible] the neck, or any other important structures. In spite of [illegible] difficulties [and dangers of the operation, such as hæmorrhage, interference with the vagus nerve, &c., the patients usually do well and only very rarely exhibit any untoward post-operative complications. The cases which I wish to record are very good illustrations of the possible complications of the operation, depending entirely upon the condition in which the thyroid gland is left after it.

CASE 1.—The first patient was an Egyptian girl, aged 12 years, who was a deaf-mute but who in other respects appeared to be quite intelligent and well developed. As is unfortunately only too common with Egyptians of even average intelligence, no satisfactory history as to the duration and rate of growth of the tumour [illegible] obtained, the only relative of the patient living at [illegible] from Cairo. From an examination o[illegible] (Fig. 1) it will be seen that the appearances were those of a typical tri-lobed goitre, which was not adherent either to the skin or to the deep structures of the neck. There was no dyspnœa or dysphagia or other sign of pressure, but all the movements of the neck were considerably interfered with owing to the size of the goitre.

The removal of the mass after the skin of the front of the neck had been raised in one large apron-shaped flap presented no special difficulty; indeed, it was so easy to shell out all three lobes that I was much tempted to remove them entirely. However, a piece of the isthmus of the size of a walnut was left in the middle line of the neck, and after careful ligature of all the divided vessels the skin flap was sutured with a continuous silk suture and the whole wound was thus closed without drainage. Two days after the operation the patient had a sudden attack of dyspnœa and presented all the symptoms of severe laryngeal spasm. The spasm subsided after a few hours and did not recur until many days later. On the following morning all the signs of early and not very marked tetany were observed in the hands and feet and a thyroid tabloid of five grains was ordered to be given twice a day. During the next two days the tetany persisted and became much more marked and then it gradually disappeared.

FIG. 1.



Showing multiple-lobed goitre.

It was noticed that the patient had become very pale and anæmic since the operation, but there was no sign of myxœdema anywhere, either at this time or subsequently. In spite also of forced feeding she became more and more [illegible] continued for a week, [illegible] other tonics were [illegible] that the symptoms [illegible] due to the inability of the remaining piece of thyroid gland to supply sufficient secretion for the needs of the organism for the first few days after the operation—that is, until it had become accustomed to the extra work thrown upon it by the removal of the rest of the gland—and that coincident with the disappearance of the tetany and the absence of other symptoms of insufficiency it had then taken over its new duties and was now supplying all the secretion that was necessary. However, on the twelfth day the tetany returned and the tabloids were again exhibited but with little or no effect; for, though the spasms were not so frequent, they were more severe than before and were confined mainly to the extremities but with [illegible]atory seizures The patient was bathed in [illegible] the attacks and the emaciation and general [illegible] more and more marked. Finally, 24 days after the operation she died after a very severe and almost general seizure which particularly involved the respiratory muscles.

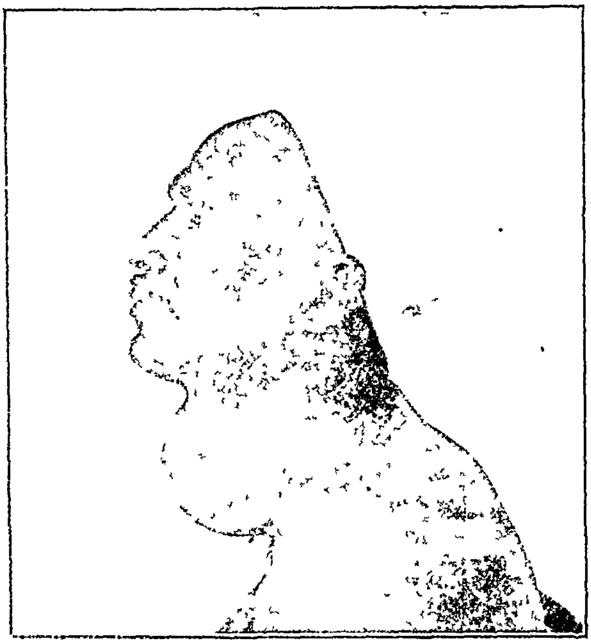
The cause of death was post-operative tetany of the respiratory muscles This tetany in the early stage resembled hysteria and were it not for the attendant circumstances of the case it might easily have been mistaken for it; while later the spasms became so severe as to simulate tetanus At the post-mortem examination no trace of thyroid substance could be found in the neck and it was quite obvious that the small piece that had been left at the operation had undergone complete atrophy. No lesions were found in any other organ. It is to be regretted that thyroid medication was not pushed to the extreme limit of safety in this case as it must be confessed that with the present facilities for the introduction of thyroid material into the body post-operative tetany ought to be a curable complication.

---

[22] Brit. Med. Jour., vol ii., 1899.
[23] Naturforscher Versammlung in Bremen, 1890

CASE 2.—The second case was the exact antithesis of the first and was that of a goitre of eight years' standing in a blind man, aged 24 years. As the illustration shows (Fig. 2) and as subsequent operation proved, the enlargement was confined entirely to the isthmus. It had increased rapidly in size during the last three years and was producing a certain amount of difficulty in breathing owing to direct pressure upon the trachea.

FIG. 2.



Showing single-lobed goitre.

Removal was effected in the usual way but the operation was rather difficult on account of the extreme vascularity of the mass and its firm attachments above. The only points at which the thyroid substance was divided were at either side, a very narrow pedicle connecting the enlarged isthmus with two normal lateral lobes. The structure of the mass was that of an ordinary parenchymatous goitre with considerable cystic change. Three layers of silk sutures were put in, one for the deep cervical fascia, another to draw the edges of the sterno-thyroid and sterno-hyoid muscles together in the middle line, and the third for the edges of the skin flap. A packing of sterilised gauze was placed in the cavity deep to the cervical fascia, the end being brought out of the lower end of the flap. The operation took about an hour and the patient was rather collapsed after it though not a great deal of blood had been lost. Almost as soon as the effects of the anæsthetic wore off he began to be restless and excited and both his pulse and respiration became very rapid. He was given normal saline solution by the rectum and strychnine and morphia hypodermically but without much effect, for the same evening his pulse was 144, his respirations were 52, and his temperature was 102° F. No physical signs either in the heart or the lungs could be found to account for these symptoms and Mr. Ll P. Phillips, the resident surgical officer of the Kasr-el-Aini Hospital, regarding the case as one of thyroid toxæmia very rightly removed the packing and washed out the whole cavity with saline solution and then put in a large drainage-tube. The patient's condition did not appreciably improve during the night and next morning he was drowsy and semi-conscious and the temperature reached 103°, while the pulse and the respiration maintained their former rapid rate He was then transfused by the veins with one and a half litres of normal saline solution and the wound was freely opened up and well irrigated. All to no purpose, however, for, although the restlessness was controlled by morphia, his general condition did not improve and he died 28 hours after the operation

No post-mortem examination was allowed but it seems reasonable to conclude that the cause of death was the sudden introduction of thyroid secretion into the system, absorption taking place from the cut surfaces of the isthmus, the extreme vascularity of the part accounting for the rapidity of absorption. The symptoms were not those of collapse but were exactly similar to those observed when the administration of thyroid extract has been pushed to a severe degree. In a fairly large series of cases of partial thyroidectomy I have never met with either of these complications before and they illustrate very well the opposite extremes of the possible dangers due to interference with the structure upon which we are operating.

My only other fatalities have been one case from hæmorrhage, eight hours after operation—due entirely to the neglect of a native attendant—and another from a condition which I may call "kismet" and which it will be difficult for those who work entirely among Europeans to understand. The patient was an old woman who, three weeks after the operation and when she was ready to leave hospital, refused to go out as she had no home to go to and announced her intention to die, which she did in spite of all efforts to keep her alive by food, strychnine, and stimulants. She gradually "faded away" and nothing was found post mortem to justify her dying. I have met with this "death by willing" on other occasions in hospital practice in Egypt. These cases cannot be included in the category of those in whom "the operation was a perfect success but the patient died," for neither the operation nor the condition that necessitated it was in any way responsible for the death. They were typical instances of the power of dying at will.

Cairo.

ON THE DANGER OF RAILWAY TRIPS TO HIGH ALTITUDES, ESPECIALLY FOR ELDERLY PEOPLE.[1]

BY THEODORE ZANGGER, M.D.,
LATE ASSISTANT PHYSICIAN, UNIVERSITY HOSPITAL, ZÜRICH.

OUR Alps claim their annual victims. Not only thoughtless youths but careful men who have arrived at the age of discretion succumb to accidents of various kinds, so that the deaths from such causes, often in themselves avoidable, amount to 60 per annum. Nay, even sober-minded grey-haired men who have many years since dismissed any thought of Alpine climbing, and who rightly condemn those who hazard their limbs or even their lives by undertaking difficult ascents without guides,—even these may inadvertently run great risks, as will presently be shown The great majority of the public, and even some medical men, ignore the various dangers that menace the lives of elderly persons undertaking mountain ascents—say, at elevations higher than 3300 feet above sea-level. These dangers may be summed up in two words, apoplexy and heart failure ; but instead of the latter expression it is better to use the two medical terms "thrombosis of the heart" and "embolus of the lung." The explanation of the matter is extremely simple. On the one hand, many persons have a difficulty in realising that they are getting on in years, while, on the other hand, degenerative processes may develop in the heart without causing any symptoms, and in the case of such patients incautious mountain ascents are not only dangerous to life but may even have a fatal termination. I wish to call particular attention to the circumstance that such seizures do not occur exclusively during the stay of the patients at the high altitude but may come on, either slowly or abruptly, one, two, and even three days after they have returned to the low ground. The general public, and sometimes also the medical profession, therefore fail to perceive that there is a direct connexion between the catastrophe and the high altitude. Not a few medical men are of opinion that there cannot be any such causal connexion when several days intervene between the stay at the high altitude and the onset of heart failure or apoplexy, but they are certainly in error, though I quite recognise the great difficulty of supplying direct and convincing proofs in these cases. Nothing but the careful observation of clinical facts will clear this matter up and I trust that the present contribution to the subject may stimulate others to similar investigations. Further physiological and clinical research may then succeed in clearing up some points which are as yet not fully understood.

---

[1] Abstract of a paper read before the Medical Society of Zürich on Nov. 15th, 1902.

It is well known that visits to high altitudes endanger the physical welfare of patients suffering from diseases of the circulatory and respiratory system, but it is very difficult to formulate warnings which may be of general applicability.

As regards the altitude, a difference of from 1300 to 1600 feet may act detrimentally on patients suffering from the first symptoms of heart failure, whether dependent on the condition of the endocardium or the myocardium. As far as my experience goes, this altitude, as in the case of the Uetliberg (2850 feet), situated 1500 feet above Zürich, is less harmful in such cases than the sudden and considerable differences of temperature which are more liable to occur on an exposed peak than in a valley of the same altitude. My experiences derived from Adelboden (4400 feet) go to prove that such a height cannot be considered a matter of indifference, even though the place is well sheltered by surrounding mountain peaks. Patients suffering from disease of the valves or muscle of the heart or from arterio-sclerosis with whom a residence at that elevation did not agree improved immediately if I sent them down only 1000 feet lower. It therefore seems advisable on practical grounds to fix the upper limit of indifferent altitudes at 1000 metres, or about 3300 feet above sea-level. As soon as altitudes of 2000 metres or more (over 6600 feet) are in question it is necessary to give more attention to the contra-indications and to be much more careful with the patients. At such heights disagreeable or even alarming symptoms soon make their appearance, and even become intense, in patients suffering only from the initial stages of vascular disease.

Questions relating to the limits of age present similar difficulties. Only a careful examination of each patient will enable the practitioner to give a proper opinion, for vascular changes and degenerative processes in the heart may be established soon after 30 years of age. I gather from a small treatise by Dr. Hampelin[2] that of upwards of 100 cases duly examined post mortem 25 per cent. were at ages between 30 and 40 years, 25 per cent. were between 40 and 50 years, and 33 per cent. were between 60 and 70 years. However, this refers to severe cases which ended fatally, and especially to the labouring classes, who generally have much more strain put on their vascular system than the well-to-do middle and upper classes, whereas it is with the latter that the present paper is principally concerned. As a rule vascular changes are *in these cases most frequent* between the ages of 50 and 70 years. It must be remembered that on the one hand clinical symptoms may be absent where a post-mortem examination reveals serious and important anatomical lesions and that, on the other hand, the results of the pathological investigation, even when duly aided by the microscope, may not in the least correspond to the severity of the symptoms observed during life. Practically it is only possible to estimate the degree of loss of function (*den Grad der Functionsstörung*) and to draw conclusions as to the soundness of the muscle of the heart from its capacity or incapacity for work.

I have already in THE LANCET[3] referred to the danger of high altitudes for patients affected with arterio-sclerosis and have given indications to guide the practitioner when asked for advice as to a stay at an Alpine health resort. My principal *object in the present communication is to* call attention to the danger that elderly people may incur by making railway journeys up to high altitudes. In my paper just mentioned the following sentence will be found: "Rapid ascents to a high altitude are very injurious to patients with arterio-sclerosis and the mountain railways up to 7000 feet and 10,000 feet are positively dangerous to an unsuspecting public, for many persons between the ages of 55 and 70 years consider themselves to be hale and healthy and are quite unconscious of having advanced arterio-sclerosis and, perchance, contracted kidneys." There are in Switzerland quite a number of mountain railways carrying passengers up to altitudes over 6000 feet. I have personal experience of detrimental effects produced on elderly people as soon as this limit is passed. Let me give a list of these mountains. Rigi, 5900 feet; Stanserhorn (on Lake Lucerne), 6330 feet; Schynige Platte (above Interlaken), 6660 feet; Rochers de Naye (above Montreux), 6707 feet; Scheidegg (above Grindelwald), 6770 feet; Pilatus (near Lucerne), 7010 feet; Brienzer Rothhorn (over the Lake of Brienz), 7408 feet; and Gornergrat (above Viége-Zermatt in the Valais), 9905 feet. The railway up the Jungfrau reaches at present an altitude of only 9233 feet, but next year the station Eismeer (10,332 feet) and later the stations Mönch (11,000 feet) and Jungfrau (13,366 feet) will be reached.

Notwithstanding diligent search I have been unable to discover any previous publication referring to the effects of *rapid* changes of altitude on elderly people, for balloon ascents are generally made by comparatively young or healthy individuals. The opinion has almost universally prevailed that the mere ascent to such high altitudes even in complete absence of bodily exertion must act detrimentally on human beings. This view was based on observations made during mountain ascents (as in the Himalayan Mountains), during balloon ascents, and during experiments on the effects produced by artificially rarefied air (i.e., the pneumatic cabinet). The so-called "mountain illness" (*Bergkrankheit*) which attacks healthy individuals who reach an altitude of about 10,000 feet is well known and has been carefully studied. I do not intend to enter into details here but am obliged to mention that this "mountain illness" is not only accompanied but produced by slight dilatation of the right ventricle of the heart; it is thus but a forerunner of the typical case which I shall hereafter describe. A physiologist of note, Professor Kronecker of Berne, has summarised his opinions on the subject of "mountain illness" as follows[4]: "Reduction of barometric pressure leads to congestion (Stauung) of the blood-vessels in the lungs; this impedes the flow of blood to the lungs and *causes dilatation of the right ventricle of the heart.*" When the Swiss Government was asked to sanction the making of a railway up the Jungfrau they appointed a scientific committee to examine the question, Professor Kronecker being one of the members. The summary of this report, which was published at Olten in 1890, was to the following effect: "From a scientific point of view it is not advisable to grant this application until the railway company has proved in a satisfactory manner that such ascents can be made without detriment to health." It must be admitted that the carefulness of the Swiss Government was very praiseworthy.

Mr. Guyer-Zeller who had made the application immediately set to work to collect the necessary evidence. I will [illegible] seven persons, some of whom were inhabitants of the valley of Zermatt (5314 feet) and some of Berne (1765 feet), were carried in chairs up to the summit of the Breithorn (13,685 feet). They accordingly made the ascent without physical exertion. Their circulatory and respiratory organs were carefully examined on the day before the ascent and again on the summit. I must lay especial stress on the fact that the people from Berne had spent at least 24 hours at Zermatt and had thus had the benefit of a short period of acclimatisation. The altitude that has to be taken into account is therefore the difference of altitude between the Breithorn and Zermatt, a difference of only 8371 feet and not the difference of altitude between the Breithorn and Berne, a difference of 11,920 feet. I may also mention that these 8371 feet were traversed in eight and a half hours, whereas the difference of altitude between Visp and Gornergrat (7740 feet) is now traversed by train in little more than half that space of time. This is of practical importance. Professor Kronecker came to the following conclusions: "Healthy persons do not suffer from being conveyed without any exertion on their part to an altitude of some 12,000 feet, but as soon as any, even slight, muscular action is required of them distressing, or even dangerous, symptoms of circulatory trouble supervene." He also made the following recommendation which, in my opinion, is an excellent one: "A medical man should be stationed at Scheidegg (6770 feet) who would examine any passengers at [illegible] the [illegible] the [illegible] able [illegible] observations that comfortable and leisurely conveyance (without any exertion made by the person conveyed) from Zermatt to the Breithorn, a difference of altitude of 8371 feet, during mild weather and on a day almost free from wind caused an increase of the pulse-rate, a decrease of the blood pressure, and a decrease of the vital capacity (*Vitalcapazität*) of the lungs, accompanied by obvious cyanosis. Slight exertion, such as walking 20 paces on level ground, caused the pulse-rate of the most robust guides to rise from 100 or 108 to 120 or 140 and caused that of the persons who had made the ascent in chairs to jump up to 160 per minute. These facts being known it becomes easy to understand that mountain ascents by railway may be productive of serious injury to elderly persons affected with arterio-sclerosis or degeneration of the heart, and it is no longer possible to maintain that, in contra-distinction to active climbing, the mere conveyance of persons (without exertion on their part) to high altitudes is devoid of ill-effects. Muscular activity undoubtedly puts an extra strain on the heart, but that is not the aspect of the case which is at present under consideration. The class of individuals referred to could not walk up a slope for half an hour without being brought to a standstill by symptoms of dyspnœa, palpitation, vertigo, or pain in the region of the heart. Such patients imagine that mountain railways are a great convenience, but my opinion differs from theirs, as will have been seen. Entirely without reference to the cases in which definite heart disease has been diagnosed I recommend that patients with weak hearts should do something by way of testing their vascular and respiratory system before venturing on an excursion up a mountain.

[2] Ueber Erkrankungen des Herzmuskels, Stuttgart, 1892.

[3] THE LANCET, June 17th, 1899, p. 1628.

[4] Das Project der Jungfraubahn, Zürich, [illegible]

On Dec. 21st, 1894, the Swiss Government granted the permission which enabled Mr. Guyer-Zeller[5] to commence the remarkable and gigantic work of making a railway up the Jungfrau. Nothing can be said against the granting of the permission, for all the evidence available up to the present time goes to prove that healthy persons can by this means enjoy the splendour of Alpine scenery, not only without much fatigue or expense, but also without detriment to their physical condition. It would be quite unreasonable to denounce the making of such railways merely on the ground of the risk that might be incurred by feeble and elderly persons. It is the duty of the medical profession to warn the public of possible risks and the public thus warned ought to be on their guard. By making their views widely known through the medium of the press the medical profession have fulfilled an obvious duty. It must also be remembered that the strictly medical side of the subject requires further elucidation and theoretical inferences will not be of much assistance in this. Descriptions of cases which have been carefully observed are indispensable and I must appeal to my fellow practitioners in Zermatt, Grindelwald, Lauterbrunnen, Lucerne, and other places, for such details, which they will be easily able to furnish when once their attention has been called to the matter. I shall give an account of one typical case which will serve to illustrate a dozen other instances that have come under my notice presenting symptoms sometimes even more acute but less prolonged.

Persons already recognised to be suffering from heart disease scarcely need to be warned against mountain ascents. They all know, or at least have every opportunity of knowing, the risks which they run, but it is right that medical practitioners, or rather the medical press, should insist on the necessity for caution in the case of elderly persons whose vascular system is to some degree impaired, although to all appearance they may be in good health. Such patients—for they are patients—never think of being medically examined before undertaking an ascent; they make the venture on the spur of the moment, without a thought of the possible consequences, and they even neglect to break their journey for a time at an intermediate station. Venous stasis (*venöse Stauung*) becomes slowly but surely established though quite unperceived, dilatation of the right ventricle of the heart ensues, and the blood pressure undergoes serious, perhaps rapid or even prolonged, changes. Subjective symptoms may be absent during the railway journey or during the period of stay at the summit, but if they show themselves the patient will do well to heed the warning. The heart brings its latent reserve force (*seine latenten Spannkräfte*), as Rosenbach calls it, to the front, and as soon as this is exhausted, whether at the high elevation or on the low ground, the catastrophe may ensue. It often happens that it is only after the descent that the vascular system is observed to have been overstrained and either temporarily or permanently damaged. Mountain ascents by railway involve an element of danger for all those who cannot walk up a gentle slope for an hour without feeling disagreeable symptoms, such as shortness of breath, giddiness, &c., whether the cause depends on alterations in the blood (anæmia), in the respiratory organs (emphysema, bronchitis), or in the vascular system (arterio-sclerosis, myocarditis). The majority of these ailments are met with in persons over 60 years of age. It would be going too far to forbid such persons to undertake railway excursions of this kind, but at least a warning ought to be given them and it is advisable for them to be careful. Let them commence with trial ascents of 3000 or 4000 feet above the valley before venturing up to greater elevations. In any case they must "acclimatise" themselves or become accustomed to the reduction of pressure by stoppages at intermediate stations; for instance, let them stay two or three days at Zermatt (5315 feet) before undertaking a trip up to the Gornergrat (9905 feet). Let them refrain altogether from going higher up the Jungfrau than 9000 feet, and before attempting this experiment let them become "acclimatised" by a stay at Grindelwald (3414 feet) and Scheidegg (6770 feet). Persons over 60 years of age should never undertake such trips unless with the consent of a medical man.

It would be very interesting to study the separate factors which act detrimentally on the vascular system in such cases, but they are so complex and so interwoven that it is almost impossible to consider them individually. Professor Levy remarks in a chapter on the Physiological Effects of High Altitudes[6]; "Though the effect of the Alpine climate, as a whole, on the human frame has been well studied, yet the effects of each separate factor are still very obscure." I will, however, pass some of these in review with respect at least to their bearing on the vascular system.

There can be no doubt but that the decrease of atmospheric pressure (a fall of 200 millimetres in the mercurial barometer for an ascent of 10,000 feet) is of importance. Mosso[7] could not detect any difference in the blood pressure, but it must be remembered that his observations were made on soldiers who were hardy mountaineers and were accustomed to live in high altitudes. It would be more appropriate to direct attention to the decrease of blood pressure observed by Professor Kronecker[8] in the persons whom he examined. It is most desirable that more information should be collected about the blood pressure of individuals who have returned to the low ground after a visit to high altitudes. The rarefaction of the air acts indirectly on the circulation by means of congestion of the vessels of the lung as already mentioned (Kronecker). The respiration becomes accelerated to the extent of 10 or 12 additional respirations per minute even in the complete absence of muscular activity; it becomes shallower for a time, only to increase afterwards and to surpass the original ratio. The volume of respiration (*Respirationsgrösse*) is increased even during complete rest by from 40 to 50 per cent. as compared with the corresponding volume for the same individual when on the low ground. This evidently implies extra work for the heart.

The chemical features of respiration also undergo changes. The amount of oxygen which is absorbed sinks while the respiratory quotient (*respiratorischer Coefficient*) rises. This means that the bodily tissues, inclusive of the heart, receive less than the usual amount of oxygen and it has also to be mentioned that the muscular substance of the heart is especially liable to suffer from a deficient blood-supply (Rosenbach). The quicker and more superficial the breathing is (and this is especially the case in elderly persons having an inelastic resistant thorax and suffering from emphysema) the more the want of oxygen makes itself felt. That is the reason why those who inhale only small amounts of air (only 300 or 400 cubic centimetres) at a time are predisposed to mountain sickness. The excess of carbonic acid in the blood must also act detrimentally on the nutrition of a feeble dilated heart. The direct influences on the circulation are manifold. The frequency of the heart beats increases by 20 or 40 per minute, an augmentation which may mean a great deal in the case of a weak heart. An increase in the number of heart beats from 60 per minute to 90 per minute for only five hours implies 27,000 contractions instead of 18,000, and the work performed by the heart in an identical space of time increases from 12,600 to 18,900 kilogrammemetres.

---

[5] Mr. Guyer-Zeller's death was announced in the end of 1902.

[6] Handbuch der Physikalischen Therapie, von Goldscheider und Jacob, 1901, Band i., S. 129.

[7] Der Mensch in den Hochalpen.

[8] Loc. cit.

A most important factor, which, however, I cannot find mentioned anywhere, is the reduction of the temperature of the atmosphere, especially on exposed mountain peaks. During a mountain excursion of a couple of hours there may be variations of temperature to the extent of from 30° to 60° F. Peripheral blood-vessels are apt to contract and to remain contracted, especially if no muscular exercise is being taken, as in fact happens in these cases. Such vaso-motor changes must affect the blood pressure and the distribution of the blood in the whole system, even as far as the heart. It can be easily understood that on the return to the low ground considerable oscillations of the blood pressure and perhaps a considerable rise of some duration may take place—a sequence of events which may explain the sudden occurrence of apoplexy. It must be remembered that the vessels of the brain have not yet been proved to possess vaso-motor nerves, so that just at the most vital centres of life the regulation of the blood pressure may be very inconsiderable or even altogether wanting.[9] It is therefore not surprising that a feeble heart should show insufficiency under such an unusual strain.

It will here be convenient to make a few general references to acute dilatation of the heart. This condition, our knowledge of which is principally due to English authors, is observed in young persons after infectious diseases such as pneumonia, typhoid fever, influenza, &c. It also often occurs after severe muscular exercise, especially in Switzerland during military service. In Switzerland every citizen has to serve in the army and to do military duty for a period of from three to seven weeks every two years from the age of 20 until he is 32 years old and every four years from the age of 33 until he is 45 years old. On these occasions the men are often called together from sedentary occupations and when they arrive are in a condition quite unsuited for

part every year, and I have seen hundreds of men lying about in different stages of acute exhaustion after having been called upon to make forced marches of 12 or 14 hours for several days. I question whether the interest of the State is served by thus recklessly (shall I add uselessly?) endangering the health of the troops in time of peace and I venture to suggest that my medical brethren in the army would do well to be more careful If one of them would take the trouble to study the state of the heart in a picked number of some hundreds of men before and after such manœuvres some scientifically interesting and practically useful results would no doubt be arrived at. I happen to have treated one such case eight years ago, occurring in a man, aged 22 years, a tailor, who had already done military service and who had not previously suffered from rheumatism or any other illness until in 1894 he had a slight attack of influenza. The toxins of this disease are well known to have a detrimental effect on the muscular tissue of the heart Two months afterwards he was called out for his periodical training, in the course of which, to quote his own words, "the troops had sometimes to make almost superhuman exertions, so that on one occasion the medical man attached to the regiment requested the commanding officer to stop the exercises and give the men a rest." After this training was over I discovered a very pronounced dilatation of his right ventricle with insufficiency of the tricuspid valve. I must lay especial stress on the fact that the subjective symptoms were inconsiderable and referred only to over-fatigue and palpitation. The heart beats were 86 per minute and epigastric pulsation was very distinct. Under rest and proper treatment this dilatation, together with the loud murmur over the tricuspid valve, disappeared within a fortnight; the murmurs were not heard afterwards. The pulse-rate became normal and even subnormal (60 per minute) In the following year, however (1895), he suffered from pleurisy on the right side with copious effusion which required tapping and I evacuated about four pints of clear fluid During this illness a slight dilatation of the right ventricle again occurred and while he was convalescing a systolic murmur was heard over the mitral valve probably due to anæmia; it disappeared, however, in a couple of weeks and did not return. My report on the case led to the man being discharged from further military service. I have seen him every year since then, but only on account of slight ailments. His heart has recovered completely and has remained free from murmurs. I have searched in the medical journals for records of such cases, but I have not found any except in the Vienna journal *Der Militararzt*. As may be easily understood, acute dilatation of the heart is often observed after violent and prolonged bicycle exercise, especially if the cyclists are not in training, if they have not observed moderation in the amount of fluid which they have drunk, if they have rushed up steep inclines, or if they have ridden for some time against a strong wind. As the individuals concerned are usually young persons whose cardiac muscle is in good condition the heart can, and does, respond by becoming hypertrophied, the result being that dangerous consequences are generally avoided.

It would seem at first sight impossible that dilatation of the heart should be produced in persons who have been carefully conveyed up to high altitudes without any muscular effort whatever on their part, and it would seem equally impossible that the manifestation of grave symptoms should be deferred until 24 or 36 hours after the excursion has been made. The facts, however, must be accepted as they are found in nature and I will gladly leave the explanation of them to those who are sufficiently versed in physiology and pathology. Some of the cases mentioned in the present article may be of service in this respect and records of similar ones will give additional assistance. As regards the long interval which may elapse between exposure to conditions detrimental to health and the appearance of pathological symptoms I can refer to the following facts. I have three times at the age of 38 years had occasion to overstrain my heart at bicycle exercise, my heart being apparently healthy both then and now. With the exception of an unusual sensation of fatigue which continued for a couple of hours I felt no disquieting symptoms until after the lapse of 12, 16, and 18 hours respectively. The same symptoms repeated themselves each time and I have no intention of renewing the experience. I woke between midnight and 4 A.M. with what I should call a fluttering of the heart or, if the expression is admissible, a distinct consciousness that I had a heart (an acute medical observer has said that we are unconscious of the existence of our internal organs so long as they are not out of order). I had no pain but my pulse was irregular, which is a most exceptional occurrence, and it remained so for about the space of an hour when I went to sleep again. I may also refer to the case of my patient mentioned in THE LANCET of June 17th, 1899, p 1628 He made a railway journey up the Pilatus (7000 feet) and his acute attack of angina only

In THE LANCET of Nov. 8th,

Morison has described the

who was up to the time of his illness supposed to be in good health and whose first attacks of angina pectoris occurred 12 hours or more after unusual exertion and fatigue which must have played a considerable part in the causation. The patient seldom blames the mountain journey for his sufferings and he certainly does not influence the medical man in that direction. The latter, however, finds that patients present severe subjective symptoms with corresponding objective changes after journeys by mountain railway and if he has either known the patients before or can obtain medical evidence as to their previous state of health he will have no doubt as to the sequence of cause and effect.

præcordial anguish of

these in different combinations and different degrees of intensity. Objectively, more or less dilatation of the right ventricle of the heart is discovered. That this may often be observed and should be carefully studied I gather from a letter in which a colleague in Zermatt wrote as follows in November, 1902: "I often observe dilatation of the right heart up here and consider this an indication for sending the patient immediately to the low ground." The fact that it is not uncommon for two or three different medical men to see a patient at various stages of the same illness assists in masking the connexion between cause and effect.

[9] Ferrier (Harveian Oration on the Heart and Nervous System). THE LANCET, Oct. 25th, 1902, p. 1099.

Preventive measures have already been sufficiently discussed. As regards treatment, the sending the patient down from the high altitude as soon as possible is imperatively indicated. A carriage is generally a more advisable means of conveyance than the railway, as the patient can be kept quieter. Absolute rest in bed for several days is necessary. In the event of insomnia being present wet packs well covered with flannel may be applied to the lower extremities (*Wadenwickel*) or to the abdomen (*Leibwickel*); bromides may also be given or injections of one-third or one-fourth of a grain of morphine. The heart may be stimulated with caffeine or, better still, with camphor, but not with digitalis. The bowels must act daily, aperients or enemata being resorted to if necessary. Free diaphoresis should be encouraged. Externally counter-irritants may be applied in the region of the heart and in severe cases venesection may be performed. The heart must afterwards be kept comparatively quiet for several weeks and in severe cases even for months.

As an illustration of these points I will now describe a typical case that came under my observation some months ago. The patient was 68 years of age and was a business man in comfortable circumstances. His residence was near the lake of Constance and on Sept. 5th, 1902, he took a trip with his family to Villars, a pretty health resort above Bex in the Valais, situated at an altitude of 4166 feet. For many years he had led a most regular and sober life, had taken great care of his health, and up to that time was considered to be fairly well. Five years before he had been operated on for umbilical hernia; the surgical anæsthesia was of considerable duration and he afterwards suffered from some nervous troubles which lasted for four or five weeks. Four years before he had one attack of hæmaturia which recurred only once—namely, in June, 1902—when a thorough examination was made but without any definite clue being obtained as to the seat of the mischief. There was no albumin in his urine; his heart was found to be healthy and no murmurs were heard. It must be carefully kept in mind that at Villars he had two days for acclimatisation, that he felt well, and that he took some short walks. He had a horror of cold water and he did not indulge in either cold sponging or muscular exercise, his only exercise being an hour's carriage drive twice a day. He had recently been complaining of a tired feeling in his legs which was attributed to varicose veins of some years' standing. On Sept. 7th he made an excursion by train to Bex, Gornergrat, and Zermatt, thus exposing himself within the short space of ten hours to any influences connected with the following differences of altitude—namely, between Villars and Bex, 2755 feet; between Bex and Gornergrat, 8505 feet; and between Gornergrat and Zermatt, 4625 feet. He was quite well during the trip and for the next 36 hours; it must be remembered that at Zermatt he was still at the comparatively high altitude of 5315 feet. The first symptoms showed themselves on Sept. 9th while he was taking a short walk under a hot sun after having smoked a strong cigar at an unusual hour (he generally only smokes a cigar or two in the evening). These first symptoms were very severe and consisted of dyspnœa, a sick feeling, faintness, cyanosis, and profuse cold perspiration. With difficulty he managed to return to the hotel where he was put to bed. A medical man ordered mustard plasters to be applied to the region of his heart and administered bromides and caffeine. During the night he was very uncomfortable and restless, with a pulse-rate varying from 80 to 90, but his condition improved somewhat and he returned to Villars on the following morning (Sept. 10th). It was clearly wrong to allow the patient thus again to subject himself to two new differences of altitude—namely, one of 4569 feet between Zermatt and Bex and one of 2755 feet between Bex and Villars; his medical adviser ought rather to have sent him to the Rhone valley (Bex, Martigny) or to the lake of Geneva (1230 feet). In Villars there was a violent return of the symptoms already mentioned, together with dangerous collapse, great dyspnœa, failing pulse, and bradycardia. The medical man in Villars diagnosed very considerable dilatation of the right ventricle and gave caffeine and tincture of digitalis internally with the external application of counter-irritants such as sinapisms or hot fomentations. The patient recovered to some extent but still was unable to sleep. Having been summoned by telegram to Villars I saw him on Sept. 12th, the fifth day after his disastrous railway journey, and I then made the following notes of his clinical symptoms. As already indicated, he was an elderly man. He was very thin, with ill-nourished flabby muscles; he lay flat on his back suffering from considerable dyspnœa and every now and then he raised himself up in bed to gasp for breath, after which he lay down moaning. His respirations were 36 per minute, his pulse and heart beats were 46 per minute and synchronous, and the radial arteries were slightly thickened. The cardiac impulse was in the normal position just within the mammillary line, the border of the heart projected one inch to the right side of the sternum, and my colleague at Villars said that the dilatation of the heart had previously been still more considerable. The sounds of the heart were quite clear though soft; over the aorta the second sound was accentuated. I must here mention that up to Sept. 18th *no cardiac murmur* was heard. After a loud systolic sound and a softer diastolic one there followed a lengthened pause during which it was sometimes possible to hear a few vibrations, a flutter of the heart pointing to incomplete contractions. One-half of 92 contractions of the heart were so slight as to remain imperceptible to the ear. The veins of the lower extremities were slightly enlarged. The liver projected beyond the lower border of the ribs by a hand's breadth and could be felt as a hard mass. There were signs of emphysema of the lung, but no symptoms of bronchitis. The urine was clear and free from albumin. The patient complained of a feeling of unrest which was difficult to control, of great thirst, of want of breath, and of weariness from want of sleep. He also complained of a sensation of oppression in the region of the heart which I should call præcordial discomfort; it never became so severe that the term "præcordial anguish" or its equivalent angina pectoris would have been applicable. If it was thought desirable to use the word "angina," which would correspond to the English word "anguish," the case might be called one of "angina sine dolore." Notwithstanding the general severity of the symptoms the patient never had the impression that he was in imminent danger of death. The absence of angina pectoris did not necessarily imply that his coronary arteries were intact, for as Dr. Morison has correctly remarked in THE LANCET of Nov. 1st, 1902, p. 1176, "the grossest atheromatous and calcareous changes may be met with in those vessels without their having elicited during life any feature in the syndrome of angina pectoris." The patient was kept at perfect rest until he could be removed to the low ground in a carriage, he had easily digestible food and stimulants (Bordeaux) in small quantities, and he also took camphor internally. The subsequent history of the case was as follows. The journey to Montreux was accomplished in safety, but there was little improvement in the patient's condition notwithstanding the most absolute rest, clearing of the bowels by an enema, and stimulation of the heart by camphor. The dyspnœa did not decrease, the heart beats went steadily down from 50 to 46, 42, 38, 34, and 32 per minute; the cyanosis and dilatation of the right side of the heart became worse. After two powders containing two grains of camphor and one grain of powdered digitalis, which were administered for the purpose of testing the reserve force of the heart, it made 64 or 70 contractions per minute for a couple of hours, but the pulse remained at 32 or 35 per minute, bradycardia being thereby distinctly manifested. Hydrotherapy could not be resorted to except in the form of hot fomentations applied to the præcordial region, since on account of threatening thrombosis of the heart the patient had to be kept almost immoveable on his back. I caused him to perspire freely by administering small cups of hot tea made with juniper leaves, but this relieved him for only a couple of hours.

Professor de Miéville of Lausanne saw the patient with me on Sept. 13th. He confirmed my diagnosis in every respect and also considered the prognosis to be unfavourable in the extreme. He was of opinion that the liver was not merely congested (*Stauungsleber*) but that there probably were pre-existent changes of an inflammatory nature, as the liver felt too hard for mere engorgement; this view seems, however, to have been proved erroneous by the sequel. He recommended stimulation, camphor, wet and dry cupping, and the administration of morphia in doses of one-tenth of a grain for the purpose of controlling restlessness and promoting sleep. The patient's state went, however, from bad to worse. A double venesection (the median vein being opened in the forearm) somewhat relieved the heart owing to the removal from the engorged venous system of more than five ounces of dark blue blood which coagulated very rapidly and was under the very highest pressure. A hypodermic injection of one-eighth of a grain of morphia brought no relief and Cheyne-Stokes breathing, which is of no good augury in such cases, supervened. The vital centres in the medulla were becoming affected owing to [illegible] an insufficient amount of oxygen [illegible]th the patient, although perfectly conscious, was in the utmost degree of collapse. His features were yellowish and pinched, his nose and lips were cyanosed, his arms and legs were quite cold, and the pulse was imperceptible or no pulse could be felt. His respirations were of the Cheyne-Stokes type and eight per minute; his heart beats were 22 per minute. His general state reminded me of the comparable conditions which may be observed both in adults and in infants—in adults suffering from Landry's creeping paralysis in the last stage (a case of which I described some years ago in the *Correspondenzblatt fur Schweizer Aerzte*) and in infants suffering from the acute heart failure which sometimes follows diphtheria. In order to relieve him I gave a hypodermic injection of one-third of a grain of morphia. He fell asleep in half an hour; the cardiac collapse increased and cold perspiration made its appearance, but in an hour his pulse returned (25 beats per minute) and in three hours he woke up asking for something to eat. After this he slept with but few interruptions for 24 hours, waking spontaneously at intervals of three or four hours, taking food, and then falling asleep again. He was saved. The cyanosis had improved, the heart boundary had receded by almost half an inch, and the pulse-rate increased from 25 to 30, 40, 50, and then 60, the pulse and the heart beat acting together.

As a new complication hæmaturia set in, first five and then about eight ounces of pure blood being passed instead of urine. I thought that there might be an embolus in one kidney, but in this I was mistaken. Most probably the hæmorrhage came from dilated blood-vessels in the kidneys, bladder, and even the prostate gland, for the *engouement* of the venous system was enormous, as proved by the distension of the liver. The action of the heart rose to 78, it became intermittent (for the first time), every sixth beat failing, and a systolic murmur was heard over the mitral valve. This was attributed partly to anæmia, but was also partly due to the acute dilatation of the muscular tissue of the heart. I took leave of the patient on Sept. 18th when he was no longer in imminent danger.

Dr. Vuilleumier of Territet-Montreux kindly supplied me with a *résumé* of notes giving the further history of the case. The heart's action was maintained at the rate of 80 or 90 [illegible]al times and [illegible] few hyaline [illegible]fter repeated and very careful examination. On Sept. 23rd the patient was allowed to sit up in bed. As was to be expected considerable hypostasis was found in the lower lobes of both lungs, together with catarrh. There were no symptoms of pneumonic infiltration; the temperature never exceeded 99° F. On Oct. 6th the border of the heart only reached the middle of the sternum—the *status quo ante* being thus restored after a month—and the liver no longer overlapped the border of the ribs. The patient left for home on the 14th, having previously had a carriage-drive on two occasions. I saw him in Zürich on the 18th and made notes to the following effect. His face was unusually pale but there was no longer any cyanosis. His heart beat quite regularly at the rate of 96 per minute; a soft systolic murmur over the apex of the heart still persisted; the second sound over the aorta was accentuated. The heart did not reach the right border of the sternum; the liver had receded under the ribs. The urine amounted to two pints in 12 hours and was of normal colour. There [illegible] of the right lung and [illegible] I recommended the [illegible] retire from business life. He was recommended to practise deep breathing methodically two or three times a day whilst lying on his *left* side; the intention of this was to promote the entrance of air into the right lung. He was advised to have a uniform temperature maintained in the rooms in his country house, as he declined wintering in the south. I ordered him pastilles of "fersan," a new iron preparation which gives me excellent results in anæmia. I sent a detailed account of his illness to his family physician. The patient had indeed pr[illegible] verity of Haller's dictum, that the heart is the [illegible] *moriens*.

I think that it follows clearly from this detailed [illegible] and my deductions that the patient in question owed the acute dilatation of his heart to the railway trip. A healthy heart might resist such rapid differences of altitude, one with chronic degenerative changes could not. It must also be remembered that the congestive conditions in the venous system due to varicose veins and the emphysema of the lung predisposes the patient to such an affection. There is neither any proof nor any reason to suppose that any considerable distension of the heart existed before. The fact that the heart resumed its normal dimensions is a further fairly convincing proof, but some damage obviously resulted to the heart. A report dated Nov. 18th read as follows: The hypostasis was gone, the heart murmur had disappeared, but the heart beats still varied between 80 and 90 per minute. The patient has passed a good winter and is in his usual health. I met him at a dinner party in March, 1903. I cannot tell why the hypodermic injection of a large dose of morphine acted so promptly and satisfactorily. Of course, the rest procured by sleep must not be underrated. Then, perhaps, the muscle of the heart dilated partially at maximum lost some of its *active* contractility, and thus got space for more energetic contractions to overcome the existing obstacles in the circulation. The bradycardia was most probably of muscular origin. Of late it has become usual to refer the rhythmic action of the heart principally to the muscle[10] and to speak of automatic action. Zuelzer[11] remarks that the conception of the independent action of the muscle of the heart has gained ground in pathology since von Leyden's work on the subject and that the rhythmical contraction of the heart depends on the condition of the muscle, its [illegible] (*Erregungsfähigkeit*), and capacity [illegible] muscle became relaxed the bradycardia ceased; this sufficed to establish the connexion between the disturbance of the rhythm of the heart and muscular lesion. A great many questions of interest have been barely referred to in this paper, which must be reconsidered in the light of physiological experiments and clinical reports. If my incomplete deductions stimulate others to study this question of practical importance it will have accomplished all that I desire.

Zurich.

ON THE DISCOVERY OF A SPECIES OF TRYPANOSOMA IN THE CEREBRO-SPINAL FLUID OF CASES OF SLEEPING SICKNESS.[1]

By ALDO CASTELLANI, M.D.FLORENCE.

ON Nov. 12th, 1902, when examining a specimen of cerebro-spinal fluid taken by lumbar puncture during life from a well-marked case of sleeping sickness, I was surprised to observe a living trypanosoma. Since that date I have made as many observations in this direction as possible and the results are, to my mind, sufficiently surprising to excuse me for presenting this preliminary note. These trypanosomes do not occur in large numbers, so that to find them it is necessary to draw off at least 15 cubic centimetres of the cerebro-spinal fluid. It is better to reject the first few cubic centimetres as they are apt to contain blood. When the fluid comes away clear 10 cubic centimetres are collected and centrifuged for 15 minutes. At the end of this time there is found at the bottom of the tube a slight deposit of whitish sediment and in some cases also a minute trace of blood. The liquid above the sediment is poured off and the sediment is examined under a moderately low power of the microscope. As the trypanosomes are at first fairly active they are easily detected.[2]

In 34 cases of sleeping sickness the trypanosomes were found in the cerebro-spinal fluid taken by lumbar puncture during life in 20 cases. On two occasions I also examined in the same way fluid from the lateral ventricles and in both cases found the same parasite. In blood I found the trypanosoma once with certainty; only a few patients were tested. It may be thought that the trypanosomes are found in the cerebro-spinal fluid on account of the trace of blood which sometimes forms part of the sediment. But in several cases there was no trace of blood. In 12 cases of ordinary disease the cerebro-spinal fluid taken during life by lumbar puncture in no case contained trypanosoma and it is important to note that three of these controls were cases of the usual trypanosoma fever, as described by Forde, Dutton, Manson, Daniels, and others. Here it may be remarked that trypanosoma fever is by no means uncommon among the natives in Uganda, three cases having been met with by Dr. Baker, one of the colonial surgeons here (Entebbe), within a period of three weeks. I understand that Dr. Baker is publishing this most interesting observation. It must be clearly understood that these cases of trypanosoma fever bear no resemblance in their clinical features to sleeping sickness.

[10] See von Leyden: Kurze Kritische Bemerkungen über Herznerven, Deutsche Medicinische Wochenschrift, 1893.

[11] Berliner Klinische Wochenschrift, 1900.

[1] Communicated by the Malaria Committee of the Royal Society, [illegible] 903," and read before the society [illegible]

[2] [illegible]ables which we have not printed [illegible] in the text gives all the needful points.—ED.

The trypanosoma found in the cerebro-spinal fluid of sleeping sickness does not, as far as I have been able to make out, differ materially in size and shape from the species one finds in the blood of trypanosoma fever, trypanosoma Gambiense (Dutton), but possibly it is to be differentiated from this one, because, as a rule, the micro-nucleus lies nearer the extremity and the vacuole is apparently larger. Besides, its movements are not apparently so active, but this fact might be due to the effects of the centrifugation. In case it should prove to be a new species, the trypanosoma which I have described might be called from the country where I have found it first—trypanosoma Ugandense.

Relation of the trypanosoma to sleeping sickness.—At the post-mortem examination of 80 per cent. of the cases where I found the trypanosoma during life, I grew from the blood of the heart and from the liquid of the lateral ventricles the variety of streptococcus which I described many months ago in my first note. Up to that time I had never found the trypanosoma, but this is easily explained by the fact that I did not use the technique which I have described in this note —viz, examination of a *large* quantity of liquid after a long centrifugation. Influenced by my last investigations I would suggest as a working hypothesis on which to base further investigation that sleeping sickness is due to the species of trypanosoma which I have found in the cerebro-spinal fluid of the patients in this disease and that at least in the last stages there is a concomitant streptococcus infection which plays a certain part in the course of the disease

Note by the Secretary of the Royal Society.—As so far supporting the observations by Dr. Castellani recorded in the above communication, it may be desirable to state that Colonel D. Bruce, R.A.M.C., to whom in Uganda Dr. Castellani made known his discovery of the trypanosoma and who is now continuing the investigation begun by Dr. Castellani, has sent to the Royal Society a telegram, received May 4th, stating that since Dr. Castellani left, in 38 cases of sleeping sickness he had found trypanosoma in every case in fluid obtained by lumbar puncture and that he had found trypanosoma in the blood in 12 out of 13 cases of sleeping sickness. —MICHAEL FOSTER.

CASE OF CHOREA GRAVIDARUM TREATED BY INDUCING ABORTION.

BY JOHN BENJAMIN HELLIER, M.D. LOND.,
HONORARY OBSTETRIC PHYSICIAN TO THE LEEDS INFIRMARY; LECTURER ON DISEASES OF WOMEN AND CHILDREN IN THE YORKSHIRE COLLEGE.

CHOREA gravidarum is by no means a common condition. Buist,[1] in his most careful statistical review published in 1895, had been able to collect 226 cases. In only 20 of these had delivery been induced. Hence an account of the following case, for the notes of which I am indebted to Mr. H. Tomlin and Mr. C. T. Matthews, may be of interest.

The patient, a married woman, aged 23 years, residing in the country, was admitted into the Leeds Infirmary on Dec. 1st, 1902, being about four months pregnant and suffering severely from chorea. She had lived in adequate circumstances and had always had good food and up to three years before she had enjoyed good health. Her family history was good, there being no record of rheumatism or chorea. Three years before the patient had had an attack of rheumatism which kept her in bed for three or four days, her hands and feet being swollen and painful. From this she recovered and had no recurrence. She was married in February, 1901. During her first pregnancy she had much vomiting but no other symptoms. Her first confinement took place on Dec. 5th, 1901, when a living male child was delivered by forceps and has since thriven well. Since that time she had been short of breath and had not been able to work so hard as previously. She did not suckle the child, having no milk. She ceased to menstruate at the end of August, 1902. In the early weeks of pregnancy there was no vomiting but she felt unduly tired. She dated her present attack from about the end of October. She felt increasing weakness and her husband noticed her altered facial expression. Choreic movements were marked about the middle of November and she also complained of difficulty in sleeping. She sought medical advice on Nov. 27th and was sent to the infirmary on Dec. 1st, being admitted into the medical wards under the care of Dr. A. G. Barrs. On account of her restlessness and noisiness she was placed in a private ward.

On admission she was found to be a young woman of medium stature, not badly nourished and showing the usual signs of pregnancy at four months. She manifested violent choreic movements of the arms, the head, and the face, and to a less extent of the legs and trunk. She was intelligent and cheerful and though she spoke with a hurried and whispered voice she could articulate fairly well. There was some swelling of the left wrist but she had no pain. The pulse was 120, small, and difficult to feel because of the choreic movements The respirations were about 30 and the temperature was not above 99° F. The lips were red and not dry, the tongue was moist, and the fauces were congested and sore Physical examination of the chest showed no abnormality in the lungs, but there was a slight presystolic thrill at the apex of the heart with a double bruit. There was also a systolic bruit over the pulmonary artery with accentuation and occasional reduplication of the second sound. The patient was treated medically for ten days with chloral and bromide, with paraldehyde and with trional, and then with chloral and bromide again, receiving in 24 hours as much as 90 grains each of bromide of potassium and chloral.

For the first seven days after admission there was no very marked change in her state; sometimes the movements were violent, sometimes she was quieter. She slept on the aggregate for four or five hours in the 24 and took food fairly well. On Dec. 5th Dr. Barrs asked me to see the case and we agreed that unless improvement was manifested shortly the pregnancy ought to be terminated On the 9th and 10th it was evident that the patient was worse. The pulse increased to 140 and the respirations to 32; the temperature rose to 101·2°. The patient became more restless, talked incessantly, and was slightly delirious at night. The speech had become thick and the articulation less distinct. The tongue was coated and dry and the lips were sore. It was very difficult to feed the patient, although occasionally she took food well. She slept very little. She was now transferred to the gynæcological ward and Dr H Brown, the resident obstetric officer, took charge of the case.

On Dec. 11th, at 4 P.M., the patient was anæsthetised with chloroform and placed in the lithotomy position. The genitals were shaved and carefully disinfected. The cervix was drawn down with volsellum forceps and a sterilised bougie was passed entirely into the uterus without rupturing the membranes. The vagina was then packed with iodoform gauze. The patient had a comparatively quiet night. The fœtus and placenta were expelled about 7 A.M. on the 12th, or 15 hours after the bougie had been inserted. There was no post-partum hæmorrhage. The labour pains did not cause any marked increase of the choreic movements. The fœtus, a male with well-differentiated genitals, measured 17·5 centimetres. It was of about 21 weeks' development.

For the next three days there was no improvement. The movements became violent two hours after labour and continued so. The tongue was dry and ccated and there were sordes round the lips. The temperature varied from 100·5° to 102° and the pulse was very rapid, reaching 150 or even 160. There were no signs of uterine or pelvic mischief. She was unable to answer questions. On the 14th she had a very quiet night, the movements being very slight. On the 15th the patient was very restless and was ordered 30 grains of chloralamide every four hours. She slept for eight hours on the night of the 16th. She had a morbilliform rash over the face, the arms, and the chest. The choreic movements were marked but were certainly better. On the 19th the patient was very much better, the temperature being normal and the pulse 102. The rash was gone and the uterine condition was normal. On the 22nd she had greatly improved and was removed from a private ward to the ordinary ward. She was almost free from choreic movements, her mind was clear, and her speech was much better. The bruit was almost gone from the pulmonary artery. There was still a double bruit at the apex, but this was less marked; there was also a slight presystolic thrill. On the 23rd she was ordered five minims of arsenical solution three times daily. On the 28th she was able to feed herself and was taking 40 grains of chloralamide in the 24 hours. She was able on the 29th to thread a needle and to write her name fairly well. On the 30th the chloralamide was omitted and on Jan. 20th, 1903, she was discharged cured and with no choreic movements. Since her discharge she has attended at the infirmary occasionally as an out-patient. She continues well but there are some hypertrophy of the heart and some mitral incompetence.

[1] Transactions of the Edinburgh Obstetrical Society, 1894-95.

When the patient was transferred to my care she was certainly in a very critical condition and in the opinion of both Dr. Barrs and myself the indications were strong for terminating the pregnancy. The chorea of pregnancy depends upon a condition of toxæmia. The pregnant state fosters the toxæmic condition and renders it very little amenable to treatment by drugs. To terminate the pregnancy seems a rational method of treatment. Its effect cannot be expected to be instantaneous but may develop in two or three days. The logical demonstration of the effect of inducing delivery is impaired by the fact that chloralamide was given, and given with obvious benefit, on Dec. 15th and onwards. In my opinion the improvement began before this and the patient, who had previously derived no apparent good from drug treatment, now benefited at once. At the same time I admit that chloralamide had not been tried before delivery. Still chloral and bromide had been pushed to the full and the patient was getting worse. There is practically no doubt that inducing abortion saved her life.

Chorea gravidarum is not an essentially incurable disease. Mild cases occur from time to time which clear up without serious trouble and even marked cases may recover and go to full term, but it is a very serious complication of pregnancy and if the mortality is not so high as was formerly estimated—as by Dr. Barnes who found 20 deaths in 68 cases (29·4 per cent.)—it is still very high. Buist estimates it at 17·5 per cent., Kroner at 22 per cent., and Spiegelberg[2] at 26·9 per cent. The presence of endocarditis, as in this case, is a serious factor in prognosis. No one suggests that artificial delivery is the routine treatment for all cases, but it is the treatment to be applied when chorea gravidarum threatens life. When the movements are slight, when the patient can eat and sleep well and maintains her weight, when the pulse is under 100 and there is no pyrexia, or when confinement to bed suffices to keep the patient fairly quiet and comfortable, then there are *no indications for radical measures*. When, on the other hand, the movements are violent and continue so in *spite of rest in bed and drug treatment*, when the patient cannot sleep or take food enough and is losing weight, when the mental condition is confused and there is a tendency to delirium, when there are a rise of temperature and a dry tongue, and especially when the pulse is persistently above 100 and is becoming weaker and more rapid, then the indications are complete and absolute. One thing more, however, must be said. If we wait for indications as complete and absolute as these we may find that we have waited too long. The attempt to save the fœtus may lose the patient. In chorea gravidarum, as in hyperemesis gravidarum, the cases which require interference require it in good time. In my next case I shall not wait so long as I did in the one under consideration.

As a matter of technique I greatly prefer in such a case induction of abortion by stimulating the physiological action of the uterus to a forced mechanical delivery at one sitting. Some mechanical dilatation may be useful to complete delivery, but a preliminary setting up of uterine action by the bougie is of great advantage. The fact that we have now powerful rapid mechanical dilators available does not alter this opinion.

A SIMPLE EXPEDIENT IN THE ESTIMATION OF SUGAR BY THE COPPER REDUCTION METHOD.

BY S. ARCHIBALD VASEY, F.I.C., F.C.S.

FROM time to time the original method devised by Fehling for the estimation of sugar has been modified in some way or other, chiefly with the view of making the end of the reduction process more accurately and easily observable. It is probable that accuracy is more likely to ensue when the reagents are kept as near simplicity as possible. The modifications of Fehling's original processes have consisted in the addition of reagents in which the reduced copper is soluble, so that the blue colour is discharged by the addition of the sugar solution, a clear colourless solution being finally obtained. Thus Pavy suggested adding strong ammonia and Gerrard cyanide of potassium to the Fehling mixture. Both modifications present advantages when operating upon certain fluids with sugary contents. Pavy's method works well and gives accurate results for all ordinary purposes in the case of estimating milk sugar directly in milk or glucose in urine, but the results are variable according to the ammoniacal strength of the copper solution, and it is hardly possible to keep this constant, since the solution must be used boiling. Then the ammonia fumes are troublesome. Gerrard's cyanide process has no objections of this kind but it is somewhat complicated and involves the employment of a solution of potassium cyanide which is not stable. The process, however, is accurate.

As is well known, the drawback to the original method of Fehling is the formation and suspension of red cuprous oxide in a blue solution. The oxide is so fine that it is slow [illegible] difficult to mark [illegible]s disappeared or, [illegible]pper is in the insoluble condition of cuprous oxide. It occurred to me that instead of adding a reagent to form a soluble compound with the cuprous oxide as it is produced, as in Pavy's and Gerrard's processes, an inert powder, preferably of a clear white colour, might be employed so as to entangle the precipitated oxide and carry it rapidly to the bottom of the solution and thus to leave a clear liquid above in which the faintest trace of blue could be seen. I subsequently found that precipitated chalk and later barium sulphate fulfilled this idea admirably. Lead or [illegible] inadmissable. I now proceed [illegible] quantity of Fehling's solutio[illegible] metres) suitably diluted I ad[illegible] finely precipitated calcium carbonate or barium sulphate. The mixture is then raised to the boiling point, being gently stirred with a glass rod during the whole time. The solution in which the amount of sugar is required to be known is then run in after the usual manner. It will be found that the red cuprous oxide will be deposited upon, and evenly distributed through, the chalk slime or the barium sulphate which rapidly subsides, so that the true colour of the clarified supernatant liquid is quite easily seen. In this way the exact point of transition from a trace of blue colour to a colourless solution can be sharply noted. The process is rapid and extremely accurate according to a number of estimations made by me with standard solutions of sugar, diabetic urines, wines, and other sugary fluids, and it certainly has the merit of simplicity. This modification I feel sure will be found to be very convenient in clinical practice.

PRELIMINARY NOTE ON THE USE OF CHLOROFORM IN THE PREPARATION OF VACCINE.[1]

BY ALAN B. GREEN, M.A., M.D. CANTAB.

(From the Government Lymph Laboratories.)

IT is well known that glycerine exerts an action on vaccine whereby the extraneous bacteria are eliminated in the course of a few weeks, while the specific germ undergoes no undue deterioration from the process. I have found that by the use of a solution of chloroform in distilled water the extraneous bacteria of vaccine are eliminated in from one to six hours, the specific germ remaining fully potent for vaccination. The solution of chloroform that can most advantageously be employed in the preparation of vaccine is a saturated solution in distilled water, having a strength of 1 in 200. This is the limit of such solubility.

The following method of using such solution has so far given the best results. Vaccine emulsion is first prepared by triturating vaccine pulp with distilled water. *The presence of the water is essential* in order that later chloroform may enter into solution with it. About three parts by weight of water should be mixed with one part by weight of pulp. Should a more viscid emulsion of vaccine be desired glycerine may be added without interfering with the action of the chloroform. I have found that the usual admixture of one part by weight of vaccine pulp and four parts by weight of a solution consisting of equal parts by weight of glycerine and water forms a perfectly suitable emulsion for this process. But glycerine is incapable of dissolving chloroform and the elimination of extraneous bacteria by this chloroform process is solely due to the action of chloroform water. Indeed, when the addition of glycerine to the vaccine emulsion is desired, it can be very advantageously effected after the completion of the process. The newly made vaccine emulsion to be subjected to the action of chloroform is dealt with in the following way. Sterile air is first passed through pure liquid chloroform, whereby this air becomes charged with chloroform vapour. This mixture of air and chloroform vapour is then passed through the vaccine emulsion, which is contained in a cylindrical glass vessel of test tube shape and in size suitable to the quantity of vaccine to be treated. The mixed chloroform vapour and air can be passed seriatim through a number of tubes of vaccine before it finally escapes into the outside air, and it is efficient for all of them, provided that the current be sufficiently strong to keep the contents of each tube in active movement, and that a distinct smell of chloroform be apparent at the outlet of the last tube of the series. It is essential that no liquid chloroform be allowed to pass over into the vaccine, as its presence is strongly inimical to the potency of the lymph. To obviate the chance of such an accident an overflow bottle, weighted with sterile sand, is interposed between the bottle of liquid chloroform and the tube or tubes of vaccine emulsion. By passage through it of chloroform vapour and air the water of the vaccine emulsion quickly becomes saturated with chloroform and this strength of solution is maintained so long as such passage is continued. When saturation is reached all excess of chloroform immediately escapes automatically from the vaccine. Thus the vaccine is not at any time brought into contact with a stronger solution of chloroform than 1 in 200 in water.

A rapid and marked germicidal action is exerted on the non-spore-bearing extraneous bacteria of vaccine thus treated. The extraneous bacteria most commonly found in vaccines at the Government laboratories are staphylococcus pyogenes aureus, staphylococcus pyogenes albus, staphylococcus cereus flavus, and staphylococcus cereus albus. Others which occur either in smaller numbers or less commonly are staphylococcus pyogenes citreus, proteus vulgaris, streptococcus pyogenes, sarcina lutea, and some yeasts. Emulsions which have contained as many as 100,000 extraneous micro-organisms per platinum loopful at the time of mixture have, by the action of chloroform water, become free from their presence in from one hour to six hours. This freedom is evidenced by absence of bacterial growth in aerobic and anaerobic plate cultures. The germicidal action is first exerted on the least resistant members of each species of organism present in the vaccine. Generally after the first hour or one and a half hours of the process a very few of the more resistant staphylococci—aureus and albus—remain alive; these give rise to small inhibited colonies in plate cultures and these organisms succumb in their turn after further application of the process.

By contrast, elimination in like degree of the extraneous micro-organisms of vaccine by the glycerine process rarely occurs before the fourth week after mixture and is frequently not complete until a much later period, as shown by similar plate cultures. After elimination of extraneous bacteria from chloroformed vaccines the chloroform is evaporated until no trace remains. Such evaporation is most quickly effected by passing a stream of sterile air through the emulsion.

By the above method vaccine can be brought under the influence of the germicide for such time only as suffices to kill the extraneous micro-organisms. At present, however, there is no evidence to show that more prolonged contact with 1 in 200 watery chloroform solution has any harmful effect on its potency. As in the case of glycerine, non-spore-bearing bacteria in vaccine lymph are alone killed by this process. But in some thousands of vaccines examined at the Government Lymph Laboratories the only spore-bearing organisms found in vaccine were the strictly non-pathogenic organisms of the mesenteric group—bacillus mesentericus vulgatus, bacillus mesentericus fuscus, bacillus mesentericus ruber, and bacillus subtilis—and equally non-pathogenic moulds such as penicillium glaucum.

The practical working value of the foregoing method has been clearly shown by results of vaccinations performed with vaccines which have been thus subjected to the action of chloroform. These vaccines, having been rendered free from extraneous micro-organisms, were first tested on calves and were found to give excellent results. Within a fortnight after collection from the calf and of subjection to the action of chloroform water, such vaccines have been used (after evaporation from them of all chloroform) for primary vaccinations and revaccinations with results of high "case" and "insertion" success. It would seem, therefore, that the following considerable advantages are to be gained by the use of the chloroform process:—

1. So speedy an elimination of extraneous micro-organisms is attained that vaccine, practically free from such organisms, can be distributed for use within a few hours of its collection from the calf. In times of urgent demand for large quantities of vaccine, such as occur during small-pox epidemics, this process must needs prove of great value, since the necessity for wasting some weeks for elimination of extraneous organisms by glycerine will be done away with.

2 In so far as the vaccination value of vaccine depends on the activity of a living organism deterioration of that value must occur in the course of a longer or shorter time. The potency of some vaccines, glycerinated or otherwise, becomes greatly impaired within a few weeks of collection—that is, within the time required for glycerine to exert fully its influence in eliminating extraneous organisms. Some of these vaccines may, at the time of their collection, have possessed a high vaccination value. Vaccine, characterised by this high but somewhat transient potency, can by means of the chloroform process be used at once before its activity has deteriorated, thus allowing greater economy of vaccine material than would otherwise be possible.

3. For a similar reason the chloroform process might be of considerable use in hot climates where the preservation of the potency of vaccine is frequently a matter of considerable difficulty.

Experiments are at present being made to test the duration of the potency of chloroformed vaccines. A further account of this process will be given in the report for 1902–03 of the medical officer of the Local Government Board.

In conclusion, I wish to express my indebtedness and thanks to Dr. F. R. Blaxall for the generous help and advice which he has given me. My thanks are likewise due to Mr. H. S. Fremlin, with whom I am also associated in the work of these laboratories, and to Mr. S. D. Rowland of the Jenner Institute of Preventive Medicine for help afforded me.

A NOTE ON SOME STATISTICS OF CANCER IN INDIA.

BY O. N. SALDANHA, G.M.C.M., F.A., F.Sc.,
IND. UNIVERSITY.

As regards the difference of opinion as to the relative racial prevalence of cancer, the following figures taken from the annual report of one of the Indian life assurance offices may be of some interest, though they are not sufficiently large to warrant deducing a final conclusion therefrom. Out of a total of 401 deaths among the assured 313 occurred among Hindoos, two of which were due to cancer, and out of 42 deaths among Europeans or Eurasians three were due to cancer. There were 36 deaths among Parsees, one being from cancer. Among Mahomedans there were only ten deaths and none from cancer. The cancer-rate to total mortality among the first three communities was respectively 0·6, 7·0, and 2·8 per cent.—i.e., a ratio of 12 Europeans and four and a half Parsees to one Hindoo.

As regards the comparative rarity of cancer of the stomach among the Hindoos, as was reported or assumed to be the case by several correspondents during the discussion on the subject in the columns of THE LANCET some time ago, I will mention some dietetic peculiarities of that community. I am, however, suggesting no relation of cause and effect All underdone meat and sausages, ham, cheese, and canned foods, are not popular among the Hindoos, nor among the Mussulmans for that matter. Cold meats and cold rice is not *comme il faut* among Hindoos. All meals are entirely fresh cooked; there is no stock-pot. It is only the cakes and sweetmeats that are held over for a few days. Jams, pickles, and chutnies are home-made—i e, each family makes their own supply or are presented therewith by relatives and friends.

The accompanying table shows, for each of the various races, the amount of the claims by death from cancer paid during 1901.

Disease	Hindoos (402 policies)		Europeans and Eurasians (54 policies)		Parsees (52 policies.)		Mahomedans (17 policies)		Total (525 policies)

Hammersmith.

A CASE OF LEUKÆMIA WITH CHANGE OF TYPE IN THE APPEARANCES OF THE BLOOD.

BY ROBERT WILKINSON, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

THE case is that of a married woman, aged 35 years, whose previous health had been excellent. The symptoms of the present illness came on insidiously about December, 1901, in New Zealand and chiefly consisted of gradually increasing weakness and loss of weight. A few months later enlargement of the spleen was discovered by her medical attendant, but up to the time of coming to England she had little medical attention and no regular course of treatment. In April, 1903, she started for England and during the voyage became much worse, having to be landed at Marseilles and brought overland to Calais. She arrived in England in a dangerously depressed condition and was first seen by me on May 4th, when her condition was as follows. She was cachectic-looking, with rapid, feeble pulse (120 per minute). The temperature was 102 4° F. She was very drowsy. Her appetite was fairly good. Great enlargement of the spleen was present which extended across the middle line, the lower border reaching below the level of the left iliac crest. The liver was enlarged and palpable three inches below the costal margin. There was no ascites. The heart and lungs were normal. No sensory or motor abnormality was present; the knee-jerks and other reflexes were normal. There were no enlargement of the lymphatic glands and no tenderness of the sternum or other bones. Pronounced menorrhagia was present as well as one or two small ecchymoses of the skin. The pupils were normal and sight was unimpaired. There were copious retinal hæmorrhages and swelling of the optic discs. The urine had a specific gravity of 1015; there was no albumin or sugar but there was an excess of urates.

An examination of the blood was made on May 15th by the Clinical Research Association and the following is the *verbatim* report:—"Number of red blood cells equalled
number of white blood cells
is to say, while
one-fifth of the
...
normal, the white cells are increased to almost 100 times the average number. The films show a condition of blood absolutely pathognomonic of very advanced myelocythæmia. There was much polymorphism of white cells and one kind shaded so insensibly into the other that any accurate differential count was impossible. In addition to a marked absolute increase of all kinds of white cells, the most characteristic feature was the presence of enormous numbers of myelocytes which were frequently of great size. And as a peculiar feature of this blood, lymphocytes were quite as numerous as myelocytes and there was every gradation between the two. Polynuclear cells were relatively less abundant but the relative proportion of eosinophiles and mast cells was above the average. Another feature was the presence of nucleated red cells
were both normoblasts and
predominated. The case is of
pronounced myelocythæmia we have yet encountered."

In spite of most careful nursing and gradually increasing doses of liquor arsenicalis, &c., the patient became rapidly worse and on May 17th Dr. J. Purves Stewart was called in consultation and gave a very bad prognosis. On the 23rd, eight days after the first blood examination, the blood was again examined by Dr. Purves Stewart who had the advantage of Dr. W. S. Lazarus-Barlow's opinion. Dr. Lazarus-Barlow found that there was now a typical and extreme lymphocythæmia, though here and there a myelocyte was visible. On subsequent comparison of the two films it was clear that the type of the abnormal leucocytes present in the blood had undergone a complete change which was obviously in actual progress at the time when the first blood examination was made. The patient quickly sank and died early on the morning of the 24th. Left hemiplegia came on gradually three days before death and the temperature, which had been of the irregularly remittent type, rose to 104 4° at the end. No necropsy was obtained.

The above case is worthy of being reported on account of the unusual change occurring in the blood of a case of what was apparently a pure spleno-medullary leukæmia. The complete absence of lymphatic hypertrophy was itself as conspicuous as the positive enormous enlargement of the spleen that obtained. It seems probable that this is one of those very rare cases, similar to those recorded by Seelig[1] and van der Wey,[2] in which a pre-existing myelocythæmia towards the end of life changed its type to that of lymphocythæmia.

Upper Norwood, S.E.

NOTE ON AN OUTBREAK OF MALARIA ON BOARD SHIP.

BY J. BELL, L.R.C.P. LOND., M.R.C.S. ENG.,
SUPERINTENDENT OF THE GOVERNMENT CIVIL HOSPITAL, HONG KONG.

THE following account of a serious outbreak of malaria at sea may be of interest

Two Russian torpedo-boat destroyers left home for the Far East in October last. They touched at Colombo, leaving there on April 10th for Sumatra At this port they were anchored close to the shore and the crews were allowed leave. The destroyers left on the 19th for Singapore, at which port none of the members of the crews were on shore and the boats were anchored a long way off land. On the 23rd they left for Hong-Kong, the health of the crews so far being good. On May 1st and 2nd several of the men were suddenly taken ill with high fever, headache, furred tongue, and in a few cases vomiting. Out of the total crews of 58 men 21 were affected. On the 5th these men were brought to the Civil Hospital, Hong-Kong, and were at once isolated, as the medical officer reported them as cases of "malignant influenza." Their symptoms were much the same as when first attacked, the temperature varying between 100° F. in some cases and 104° in others. The routine blood examination at once settled the diagnosis. They were all teeming with malarial parasites, in the majority of cases (18) of the malignant type and in a few of the simple tertian variety.

---

[1] Deutsches Archiv für Klinische Medicin, 1896, Heft 6.
[2] Archiv für Klinische Medicin, Band [illegible], S. 251.

The disease was no doubt acquired at Sumatra, which would give an incubation period of over 13 days, and was in all probability acquired on shore, as the captain informs me that he noticed no mosquitoes on board either boat. Under quinine all the patients recovered.

FRENCH HOSPITAL.

A CASE OF PURPURA FULMINANS.

(Under the care of Dr. GEORGE OGILVIE.)

THE patient, a French boy, aged 16 years, was admitted into the French Hospital on July 29th, 1902, with the following history. On July 26th he went for a bathe in the Serpentine at 7.30 P.M., remained in the water for a quarter of an hour, and came out feeling cold. Small purpuric spots appeared two days after on the left side of the neck and legs, and also on the tongue, and he also coughed up a small quantity of blood. These spots gradually increased in number and size, and he was sent to the hospital on the 29th. The family history showed no signs of rheumatism or syphilis, but the boy's uncle on his mother's side used to suffer from profuse epistaxis which was very difficult to control. The boy's personal history showed that he had always suffered more or less from epistaxis, and there was also a history of his being unable to stop the bleeding from a cut finger for three days.

On admission the boy was absolutely covered from head to foot with purple spots; they were more marked on the left side, varying in size from that of a pin's head to that of a shilling piece, and were most abundant on the face and neck and legs and ankles. Some spots were also visible on the inside of the cheeks and lips, and the tongue was covered with a large purple "plaque," causing it somewhat to resemble a case of "black tongue." There was a subconjunctival hæmorrhage in the left eye which covered the whole of the outer side of the eye. The temperature was 98·2° F. At 1.30 A.M. Mr. J. M. Barlet was called to the patient as he had vomited a large quantity of blood of the "coffee-ground" variety, which was followed by bright red blood, about one and a half pints in all. Previously to this he had passed a large stool, perfectly black, consisting of fæces and a large amount of blood. He was ordered ten grains of calcium chloride every four hours, but later he had another attack of vomiting, about one pint of nearly pure blood being brought up. This was followed by profuse epistaxis from the left side which was checked with ice. On visiting him next morning Mr. Barlet found him very blanched, collapsed, with a feeble rapid pulse and sighing respirations. The temperature was 99°. The hæmorrhage had almost entirely ceased. The patient was ordered ten minims of oil of turpentine, 30 grains of carbonate of bismuth, and almond mixture to half an ounce every four hours. He was given ice to suck; iced milk and soda-water and beef-tea were also ordered.

On July 31st the boy was a good deal better in the morning, there was no more hæmorrhage, the pulse was improving, and colour was returning. The temperature was 98·6°. The larger purpuric spots were passing through the ordinary stages of a bruise. The spleen and liver were not enlarged and there was no pericarditis or pleuritic effusion. The tongue had completely cleared. In the evening the left cheek was noticed to be swelling and there was some slight oozing of blood from the left upper gum. He remained well until the evening of August 2nd, when at about 5.30 epistaxis began from the left nostril, which could not be controlled by any means at hand—ice, hazeline, calcium chloride, and plugging of the anterior and posterior nares being all unsuccessfully tried—but the hæmorrhage finally ceased about 10 o'clock, the boy having lost about three-quarters of a pint of blood by the nose and having also vomited about one and a half pints of fluid mixed with "coffee-ground" material. He was very weak and blanched. The pulse was 120 and the temperature was 98°. He slept well, but epistaxis recommenced at 9 30 A.M. and was not checked until 3.30 P.M. by plugging the posterior and anterior nares with gauze soaked in adrenalin, of which he was also given 20 minims by the mouth. The boy was of a livid greyish colour and looking very bad. The pulse ranged from 130 to 148 and the temperature was 98·2°. The blood was examined microscopically on this day with the following result. By examining 15 squares, the number of red corpuscles was 54¼ per cent. Very slight increase in the number of leucocytes was present. There was no poikilocytosis. On examining the eyes with the ophthalmoscope some hæmorrhages were discovered round the left disc, some of them with whitish spots in the centre, but none at all in the right eye. From August 5th to 10th the patient had constant oozing from the left nostril of blood which latterly had become simply a watery fluid resembling serum. On the 11th he said that he felt well and very hungry, and from this date onward he rapidly recovered and was sent to the French convalescent home at Brighton on Sept. 2nd, returning thence three weeks later looking and feeling completely well.

Remarks by Mr. BARLET.—The interest of this case lies in the seemingly very trifling immediate exciting cause of the severe disturbance to which the boy was subjected, the rapid onset of the attack, and the fact that the hæmorrhages were always more marked on the left side than on the right. As to the original cause of the attack, it is somewhat difficult to be certain what this was, as there was no history of rheumatism or scarlet fever, which are sometimes predisposing causes, and also there were no swelling of any joint and no elevation of temperature as usually occurs in a rheumatic case. On the other hand, there was a distinct history of hæmophilia, both in the patient himself and in the case of his maternal uncle, so that I think the primary cause of the malady must be put down to the inherent hæmophilic tendency of the boy, and the immediate exciting cause to the shock of the cold water.

This case resembles that mentioned by Surgeon-Captain J. Fayrer in the *British Journal of Dermatology* for March, 1896, the onset being just as sudden but the results in this case being not so severe.

MANCHESTER UNION HOSPITAL.

A CASE OF CHYLOUS ASCITES.

(Under the care of Mr. ARTHUR H. BURGESS.)

THE patient, a man, aged 59 years, was admitted into the Manchester Union Hospital on March 24th, 1903. He had always enjoyed good health until ten weeks before admission, when he suffered from pain in the epigastric and left hypochondriac regions, constant and dragging in character, and uninfluenced by the taking of food. He at first vomited only occasionally but latterly very frequently. He had lost considerably in weight and during the three preceding days the abdomen had become rapidly distended. On admission the facial aspect at once suggested the existence of some malignant disease. The patient was extremely emaciated and there was general bronzing of the skin. The appetite was lost, the tongue was thickly furred, and he vomited after everything that he took. The abdomen was tensely distended with fluid and was dull everywhere to percussion except in the epigastric region where some tenderness on deep pressure was noted.

On March 26th the abdomen was tapped and seven and a half pints of a milky fluid were withdrawn, after which a careful palpation failed to reveal any definite tumour. The fluid had a specific gravity of 1015 was alkaline, odourless, and contained albumin but not sugar, did not coagulate spontaneously, and a microscopic examination showed numerous finely divided particles of fat, some finer granules probably of a proteid nature, and a few granular epithelial cells and degenerating leucocytes. On March 31st nine pints, and on April 13th 11 pints, of fluid with similar characters were withdrawn. Emaciation steadily increased and death from exhaustion occurred on April 24th.

Necropsy.—On post-mortem examination a scirrhous carcinoma, which had commenced in the head of the pancreas, was found and had involved the right suprarenal capsule, the commencement of the thoracic duct, and the wall of the inferior vena cava itself for a small extent. The pylorus had evidently been compressed, the stomach was dilated, and the gall-bladder was distended with bile. The chyle vessels were evident but no actual rupture could be demonstrated. Small areas of fat necrosis were present about the pancreas and on the under surface of the diaphragm and the liver was studded with small secondary growths.

Remarks by Mr. BURGESS.—A distinction is to be drawn between true chylous ascites and "chyliform ascites," a less rare condition in which the milky appearance of the fluid is due to fat particles derived from the degeneration of the cells of a malignant growth or an inflammatory effusion and not from the chyle vessels or the thoracic duct Microscopically the fat in chyliform ascites is in the form of large globules either free or contained within the degenerating cells, whereas in true chylous ascites only free finely divided particles of fat are met with. Obstruction to the thoracic duct only occasionally results in chylous ascites owing to the freedom of the collateral circulation, and malignant disease invading the duct and the receptaculum chyli has been observed without chylous ascites coexisting. Should collateral circulation fail to become established the pressure in the tributaries of the thoracic duct is increased and a transudation of chyle takes place into the peritoneum; or even a gross lesion, such as rupture or perforation of a chyle vessel, may allow of a direct escape of its contents.

GOCULDASS TEJPAL HOSPITAL, BOMBAY.

A CASE OF STRANGULATED INGUINAL HERNIA; PERFORATION OF THE BOWEL; RESECTION OF SEVEN INCHES OF GANGRENOUS GUT; RECOVERY.

(Under the care of Lieutenant-Colonel W. H. BURKE, I.M.S.)

A FAIRLY robust Mahomedan, aged 30 years, was admitted to the Goculdass Tejpal Hospital on the afternoon of March 30th, 1903. The patient stated that three days before admission while walking with a heavy load on his head he felt a sensation of something having given way and simultaneously felt severe pain and noticed a swelling on the right side of his scrotum. He stated that this was the third time that the hernia had come down, but that on the two previous occasions he had been able to return it and that he wore an improvised suspensory bandage to keep it in place. He stated that the bowels had been constipated since the hernia came down. On the night of his admission the patient was very restless and vomiting of a stercoraceous character set in. He was seen by Lieutenant-Colonel Burke on the morning of the 31st and at 11.30 A.M. was put under the influence of chloroform.

On opening the sac a quantity of liquid fæces escaped. The hernia was found to be a large enterocele containing many coils of ileum much inflamed and matted together, while one loop was in a gangrenous condition, and in this portion a perforation of the gut had taken place. After freeing the constriction, which was at the internal abdominal ring, Lieutenant-Colonel Burke decided to resect the whole of this gangrenous gut and to suture the cut ends. The mesentery was divided gradually and was ligatured piecemeal with catgut sutures. The cut ends of the gut were brought into careful apposition by a series of catgut Lembert's sutures, after which the united gut was inflated like a bicycle tube. The whole hernia was then returned cautiously into the abdomen and the sac was divided above and closed with catgut sutures and returned into the abdomen, and the pillars of the ring were sutured with two deep silkworm gut sutures. A part only of the lower portion of the sac was removed and, contrary to his usual practice, Lieutenant-Colonel Burke did not dissect out the whole sac, as the patient's condition was such as to indicate the advisability of rapidly terminating the operation. A small rubber drainage-tube was put in and a counter opening was made in the scrotum below. The wound was then closed, silkworm gut being used for the buried sutures and silk for the skin sutures. The antiseptic used before opening the sac was biniodide of mercury; afterwards boric acid and saline solution were employed. One hypodermic injection of digitalis and ether was given during the operation.

The patient was fed entirely by enemata (eggs, milk, and brandy) for four and a half days and on the evening of the fifth day a drachm of Brand's essence of beef was given every three hours. On the sixth day besides this he was allowed by the mouth an ounce of a mixture of one part of cream to two parts of barley water. On the ninth day he was given four ounces of Benger's food every two hours in addition. The nutrient enemata were gradually discontinued, while his food by the mouth was gradually increased, but he did not resume his ordinary diet until four weeks after the operation. During the first 24 hours after the operation the patient passed five stools which were offensive and contained blood-stained serum, but from that time the stools became normal in appearance and free from abnormal fœtor.

The wound was dressed on April 1st and the drainage tube was removed; subsequently it was dressed every third day and finally every fourth day only. There was no suppuration; the patient never complained of any pain. A little thickening remains around the cord where the lower portion of the sac was left; the hernial opening is apparently permanently closed. The patient walked on the twenty-seventh day and left the hospital on May 5th. The temperature after the operation never rose above 100° F. and it reached that point on two occasions only; it was usually normal or subnormal.

Remarks by Lieutenant-Colonel BURKE.—I consider that this case is worth reporting as the result was much better than what I could have expected if I had followed the course usually adopted in a case such as I have described—viz., the removal of the gangrenous gut and the making of an artificial anus, which would either have remained or have had to be dealt with by a subsequent partial laparotomy with greater resultant tendency to hernia. Mr. William Thorburn,[1] in an interesting paper on an analysis of 110 operations for strangulated hernia, says: "The condition of the intestine varied within the widest limits, *but actual gangrene or perforation had occurred in ten instances only*"; also that in nine of [illegible] by Mr. Thorburn was resection of the gut practised and both of these cases died within a few hours. I hope, therefore, that this case may be of some interest to the profession.

I may add that I was assisted at the operation by my house surgeon, Assistant-Surgeon Lafond, and for the careful nursing of the case I am indebted to charge-nurse Flynn.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Exhibition of Specimens.—Chorion epithelioma.

A MEETING of this society was held on June 3rd, Dr. EDWARD MALINS, the President, being in the chair.

Specimens were shown by Lieutenant Colonel A. J. STURMER, I.M.S., Dr. F. W. N. HAULTAIN (Edinburgh), Dr. P. HORROCKS, Dr. H. BRIGGS (Liverpool), Dr. T. G. STEVENS, Dr. J. M. MUNRO KERR (Glasgow), Dr. F. W. [illegible] on Chorion- [illegible] theliomatous [illegible] stomata and gave a demonstration illustrated by specimens and lantern slides. Dr. Teacher discussed and illustrated by drawings and photographs of microscopic preparations the nature and origin of chorion-epithelioma and its relations to the placenta.

---

[1] Brit. Med. Jour., April 25th, 1903.

showed a girl, aged nine years, with a large Post-Pharyngeal Swelling which had been first noticed nine months previously and had latterly increased in size to such an extent as to cause some difficulty in breathing during sleep. A number of enlarged glands were present below the angle of the jaw on the right side These had been noticed shortly after an attack of measles three years previously. The child appeared to be in good health and no family history of tubercle was available. Mr. Waggett said he believed the swelling to be a broken-down tuberculous mass.—Dr. E. Furniss Potter showed a case (previously exhibited at the last meeting) of a man who had had a large Swelling on the Right Side of the Naso-pharynx which completely obscured the right choana, in which the diagnosis was uncertain (possibly malignant disease or gumma). Under the administration of iodide of potassium the swelling had completely disappeared.—Dr. V. H. Wyatt Wingrave showed a case of Supranasal Cyst in an Infant, aged 15 months.—Dr. L. H. Pegler exhibited a section of Recurrent Growth of the Septum.—Mr. P. de Santi showed (1) a case of Gumma of the Epiglottis which had disappeared rapidly under the administration of iodide of potassium; and (2) a specimen of a large Fibro-lipoma of the Larynx.—Mr. F. J. Steward showed (1) a case of Infiltration of the Soft Palate of doubtful nature; and (2) a specimen of Epithelioma of the Pyriform Sinus.—Dr. W. H. Kelson showed a case of Laryngeal Fistula. The patient was a man, aged 58 years, who had cut his throat in November last.—Dr. H. L. Lack showed (1) a case of Thickening of the Left Vocal Cord with deficient movement of some months' duration; and (2) a case of Multiple Sinus Suppuration showing the results after operation on the sphenoidal sinus with a new instrument.—Dr. H. Tilley showed a boy, aged six years, with a freely moveable Pedunculated Tumour of the size of a Tangerine orange growing from the right tonsillar region. The tumour had been first noticed two months previously. Since that period it had been twice removed but had rapidly recurred. It did not bleed when manipulated. There was a small hard gland freely moveable behind the angle of the right jaw.—Sir Felix Semon was of opinion, having regard to the rapid recurrence after removal and the present appearance, that this would be found to be a malignant growth.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on June 9th, Sir W. J. Collins, the President, being in the chair, when the adjourned discussion upon Dr. J. G. Garson s paper on the Position of Medical Jurisprudence in London, especially in Reference to the Investigation of Cases of Death from Violence, was continued, followed by a paper by Dr. W. Wynn Westcott on the Overlying of Infants. A paper by Dr. P. Smith on the Workmen's Compensation Act and one by Mr. R Henslowe Wellington on the Recent Southwark Poisoning Trial made up an interesting agenda which brought the session of this newly organised society to a close.

Reviews and Notices of Books.

The Elements of Pathological Anatomy and Histology for Students. By WALTER SYDNEY LAZARUS-BARLOW, B A., B.C., M.D. Cantab., F.R.C.P. Lond., Pathologist and Lecturer on Pathology at the Westminster Hospital. London: J. and A. Churchill. 1903. Pp. 705 Price 24*s.*

AS is explained by the title this text-book is intended to introduce the student to the study of pathological anatomy and histology. The author believes (and we agree with him) that it is better to explain fully the main types of pathological change than to attempt to give a description of numerous subvarieties or, in other words, that the teaching of the principles governing variations is of more use, particularly in pathology, than the teaching of the names and appearances of the numerous subvarieties themselves.

The book is divided into two parts; the first deals with General Pathological Anatomy and Histology and the second is concerned with the Pathological Anatomy and Histology of Special Organs and Tissues. Each part is further subdivided into sections instead of into chapters. The retrograde changes are first considered and an excellent account is given of atrophy and hypertrophy, the fatty change, cloudy swelling, the lardaceous change, and other pathological conditions connected with degenerative processes, including gangrene and caseation. These subjects present considerable difficulties to the student for their full comprehension; Dr. Lazarus-Barlow, however, describes them in such lucid terms that the reader has no difficulty in grasping his meaning. Obscure terms are avoided and purely theoretical questions are but lightly touched upon.

Section II. on Inflammation will be found to contain a mass of information. After a consideration of the "cardinal signs" of inflammation, "redness, swelling, heat, pain, and impairment of function," some interesting remarks are made on "cellular changes in inflammation," chemiotaxis, and phagocytosis. The student will also find much material for study under the heading, "Types of Inflammation." The classification adopted is a comprehensive and practical one: (*a*) infective; (*b*) specific; (*c*) acute; (*d*) chronic; (*e*) interstitial and parenchymatous; and (*f*) catarrhal inflammation. Then follow sections on the Sequels of Inflammation, the Anatomical and Histological Appearances of certain Specific Inflammations, and the Chronic Fibroses. All of these conditions are ably and fully described.

The description of New Growths or Neoplasms occupies five sections. In a text-book of pathological anatomy and histology the value of the work largely depends upon the nature of the illustrations or perhaps it would be better expressed by saying that the value of such a work is greatly increased if the illustrations are not only numerous but are true to nature. Dr. Lazarus-Barlow may certainly be congratulated on the success that has attended his efforts in this direction Photography has not been used in making the microscopical drawings; Dr. Lazarus-Barlow maintains that the interpretation of micro-photographs needs special training which the student has not had. We consider that he is quite right in his contention and that micro-photographs for teaching purposes have proved distinctly disappointing. The drawings for this work have been made by a non-medical artist (the author's wife), in order that they may represent faithfully the appearances as seen by the elementary student when looking down the microscope and are not semi-diagrammatic. The drawings are beautifully executed and are perfectly true to the originals. The lack of resemblance between many drawings in text-books and corresponding microscopic sections given in class seems so great to students that the illustrations are often more of a hindrance than a help, but this statement by no means holds good with regard to the work now under consideration. We have made these remarks at this stage of our review as they apply particularly to the representation of microscopic sections of new growths. Without such illustrations the student would find it impossible to realise the conditions which were being described. The classification of neoplasms here adopted is a good one and one well adapted for the instruction of students. In addition to illustrations showing the structure of the more common growths there are some very good drawings of sections of capillary and venous angioma, glioma, rhabdomyosarcoma, leiomyoma, and papillomatous cystadenoma.

In Part II. the Pathological Anatomy and Histology of the Special Organs and Tissues are described, commencing with the pathological histology of the blood. The changes in number and appearance of the red and white cells which occur in diseased conditions are clearly and fully set forth. Much stress is now laid on the various forms of leucocytes which may present themselves as aids to both diagnosis and prognosis and it is desirable that the student should acquire some knowledge of the subject. In the section devoted to this matter the results of the most modern researches are recorded, all doubtful and obscure points being excluded.

In the next section the changes affecting the Heart, Pericardium, Arteries, Veins, and Lymph Channels are described. As the author points out, in most instances all these parts of the vascular system are affected together, but for convenience of description it is certainly preferable that the diseases of each should be taken separately. The morbid conditions which may attack the endocardium are most lucidly described. The remarks on ulcerative endocarditis, however, do not, in our opinion, maintain the high standard which is so marked throughout most of the work. The varieties of the affection are not sufficiently dwelt upon, so that the distinction between primary and secondary infective endocarditis is almost lost sight of.

The section on the Pathological Anatomy and Histology of the Bones gives evidence of the care which has been bestowed on a subject which presents great difficulties to the student. The same may be said of the following section which deals with Affections of the Joints, Muscles, Tendons, and Bursæ. The pathological changes undergone by the joints are of the most diverse nature but Dr. Lazarus-Barlow has succeeded in describing these changes in terms which convey a maximum of information.

The Diseases of the Digestive and Respiratory Tracts and of the Urinary Organs are also most ably considered and sections are also to be found on Morbid Changes which occur in connexion with the Skin and its Appendages and in the Eye and Ear, the final section of this volume being devoted to Affections of the Nervous System.

Taking the work as a whole, we consider it one of the best text-books on pathological anatomy and histology which we have read and we can cordially recommend its use to students preparing for examinations and to practitioners who wish to refresh their memory on the subjects with which the book is concerned.

Diseases of the Skin: their Description, Pathology, Diagnosis, and Treatment. With Special Reference to the Skin Eruptions of Children and an Analysis of 15,000 Cases of Skin Disease. By H. RADCLIFFE CROCKER, M.D., F.R.C.P. Lond., Physician for Diseases of the Skin in University College Hospital, &c. Third edition, with Four Plates and 112 Illustrations. London: H. K. Lewis. 1903. Vol. I., pp. xxxii. and 672; Vol II., pp. 715. Price 28*s*. net.

IT is always a pleasure to read a work written by one who is a master of his subject and the perusal of this edition of this work would convince any member of the medical profession that it was indeed the production of an authority on dermatology. Even when the first edition of the work appeared in 1888 it was at once recognised as a standard work of dermatology and, in fact, it rapidly took its rightful place as the most important treatise on that subject which had ever issued from the British press. The second edition seemed but to enhance, if that were possible, the reputation achieved by the first and we feel sure that all competent judges, both in this country and elsewhere, will agree in looking upon it in its third edition as the greatest, most thorough, and most trustworthy treatise on the diseases of the skin.

It is very curious to consider the attitude maintained by a large proportion of the medical public towards dermatology. Diseases of the skin are looked upon as inscrutable mysteries; eczema and psoriasis and a few other of the commoner cutaneous diseases may be recognised and treated, but in the diagnosis and treatment of any of the diseases less frequently seen the average medical man at once feels himself out of his depth. This state of things should not be and it is to be attributed partly to the somewhat elaborate nomenclature by which nearly every cutaneous disease has at least two or three names and most of the names are applicable to several distinct diseases. One great cause of the difficulty which many find in dermatology is that we are able to distinguish many more forms of disease as the skin is exposed to view than would be possible in the case of an internal organ. There is, however, no department of medicine in which a fair knowledge can be more readily obtained and a very little study devoted to dermatology would be amply repaid.

At the present time there is no dearth of useful text-books and a careful study of any of them would be followed by a great increase of the interest with which the medical practitioner meets with a case of disease of the skin. Many rare diseases would be recognised which are now readily and hastily included under "eczema" and dermatological science would benefit by a widening of our knowledge. The recent increase in the extent of the science of cutaneous disease is evidenced by the increase in the size of the work under notice. Formerly it was contained in a single volume but now it has been found necessary to divide it into two Many new articles have been added and most of these deal with "new" diseases and some of them by no means unimportant.

A strong point in this work has always been the histology of cutaneous disease, for this is a department of dermatology in which the author has done much original work, and the treatment is given with especial fulness and care A very useful feature is the copious bibliography which is given with each disease, so that the reader is able readily to refer to the original articles if he wishes to obtain further information.

Dr. Crocker has analysed 15,000 cases of skin disease of which 10,000 occurred in his hospital practice and 5000 in his private practice. It is of interest to compare the relative frequency of various skin diseases in the two classes, but as the author points out there are many modifying factors which prevent the two sets of numbers being really representative of the relative frequency of disease in the poorer and richer classes of the community. For few patients go to a consultant who have not already been treated by their family practitioner, so that the private cases are representative rather of the more severe and inveterate cases than of skin lesions as they occur among the wealthy.

We may say, in conclusion, that the chief characteristic of Dr. Crocker's work is the well-balanced judgment which it manifests. Whilst he describes all the theories of etiology and all the methods of treatment which have been advocated he is able from the wide extent of his experience to weigh carefully the arguments advanced and the claims made and to express an opinion which accurately represents the present condition of our knowledge. We extend a cordial welcome to the third edition.

The Surgical Diseases of the Genito-Urinary Organs. By E. L. KEYES, A.M., M.D., LL.D., Consulting Surgeon to the Bellevue and the Skin and Cancer Hospitals, Surgeon to St. Elizabeth Hospital, &c.; and E. L. KEYES, Jun., A.B., M.D., Ph.D., Lecturer on Genito-Urinary Surgery, New York Polyclinic Medical School and Hospital, Surgeon to the Out-patient Department, St. Vincent's Hospital, &c. With 174 Illustrations in the text and ten Plates, eight of which are coloured. London and New York: D. Appleton and Co. 1903. Pp. 827.

IN 1867 appeared van Buren and Keyes's treatise on Genito-Urinary Disease and Syphilis and in 1888 appeared a much modified second edition, and this volume now appears representing the third edition with a limitation of its scope, because the subject of syphilis has been excluded, for though it is a genital disease in its usual mode of infection, it is not genital in its mode of expression and therefore has no necessary connexion with the genito-urinary tract. On the other hand, gonorrhœa has been nuclei will be developed. After further staining the film may be washed in distilled water, dried in air, and mounted in xylol balsam.

(1) LECITHOL; AND (2) GONOSAN.

(THOMAS CHRISTY AND CO., 4, 10, AND 12, OLD SWAN-LANE, UPPER THAMES-STREET, LONDON, E.C.)

(1) We have received specimens of "perles" each of which contains 0·05 gramme of lecithol or ovo-lecithin dissolved in olive oil. The value of ovo-lecithin as an organic phosphorus compound in diseases of nervous origin is well known. Tablets of chocolate are also prepared suitable for administering ovo-lecithin to children. Each "square" contains 0·05 gramme of ovo-lecithin. (2) "Gonosan" is the ugly compound name given to a solution of the essential resins of kava-kava, the root of *Piper methysticum*, in pure sandalwood oil. The root has been used from time immemorial in the Polynesian islands for gonorrhœa. The combination is said to diminish pain, to hasten the disappearance of the discharge, and to prevent complications.

GLEN SPEY GLENLIVET WHISKY.

(W. AND A. GILBEY, LTD., THE PANTHEON, OXFORD-STREET, LONDON, W.)

The analysis of this whisky was as follows: extractives, 0·36 per cent.; alcohol, by weight 41·30 per cent., by volume 48·75 per cent., equal to proof spirit 85·43 per cent. The whisky contained the following amounts of secondary constituents recorded in grammes per hectolitre of absolute alcohol present: acidity reckoned as acetic acid, 84·42; aldehydes, 10·05; furfural, 2·67; ethers reckoned as ethyl acetate, 79·59; and higher alcohols, 201·00. These results of analysis are thus in favour of the statement on the label being an honest description—that is, that the whisky is a pure malt spirit distilled exclusively from barley. The age is stated to be six years and our analysis at any rate indicates an amount of storage sufficient to make the whisky mature and free from the injurious products of new whisky. The flavour is decidedly malty and smoky though soft and mellow. The evidence of both the palate and chemical analysis is thoroughly in accordance with the description given of the whisky on the label of the bottle; it is a matured all barley-malt whisky.

LAMA QUINA WINE.

(GRAINGER AND SON, 21, MINCING-LANE, LONDON, E.C.)

This wine is described as "*vin tonique naturel.*" It is a syrupy red wine of port style, showing a similar alcoholic strength. It is slightly bitter to the taste and contains cinchona bark extractives. Analysis gave the following results: alcohol, by weight 21·30 per cent., by volume 26·04 per cent., equal to proof spirit 45·63 per cent.; extractives, 12·81 per cent.; mineral matter, 0·31 per cent.; sugar, 10·40 per cent. It is stated "*ce vin est pur sans addition d'alcool,*" which cannot strictly be the case since all port wine is fortified and the strength of Lama Quina wine is far beyond that which normal fermentation can yield. As a rule, we do not approve of "medicated" wines; when the patient requires a drug it should be prescribed for him by a qualified medical man, when he requires wine he will be wiser to get the pure article unmedicated.

TRISCUIT.

(THE SHREDDED WHEAT CO., 6 AND 8, EASTCHEAP, LONDON, E.C.)

The "triscuit" forms a palatable and nourishing article of diet and the statement that it consists of the whole wheat berry is borne out by our analysis. Further, in the course of preparation part of its nourishing constituents is converted into a soluble state. The "triscuit" consists of a series, so to speak, of wheat filaments interlaced in such a way as to present the appearance of a lid of a miniature wicker basket. Our analysis gave the following results: moisture, 7·30 per cent.; starch, 66·27 per cent.; soluble starch, dextrin, &c., 9·00 per cent.; proteids, 13·93 per cent.; fat, 2·20 per cent.; and mineral matter, 1·30 per cent. The "triscuit" is somewhat hard and crisp which should be a dietetic advantage since it requires complete mastication before it can be swallowed, in the same way as does dry toast or stale bread. The flavour is "wheaten" and "nutty." The analysis shows that "triscuit" is an entirely unimpoverished wheat food.

MALTA VITA FOOD.

(THE MALTA VITA PURE FOOD CO., 102, FENCHURCH STREET, LONDON, E.C.)

According to our analysis and examination "malta vita" consists of a cereal food modified by malting and cooking The carbohydrates are to a very large extent easily soluble in cold water. The preparation consists of crisp flakes which have been browned by baking. It has a very pleasant biscuit-like flavour. The results of our analysis were as follows: moisture, 7·00 per cent.; starch and dextrin, 59·31 per cent.; maltose, 14·28 per cent.; proteid, 14·55 per cent.; fat, 2·16 per cent.; and mineral matter, 2·70 per cent. This analysis is satisfactory and shows that the food contains an excellent proportion of all classes of nutritive material.

CHELTINE SOLUBLE MALTOSE FOOD.

(CHELTINE FOODS, LIMITED, CHELTINE WORKS, CHELTENHAM.)

We find this food, according to our analysis, to be correctly described and no exception can be taken to the claims made in regard to its suitability for infants and invalids when prepared in the way directed. The food is almost entirely soluble in water and contains no starch. Our analysis gave the following results: moisture, 3·90 per cent.; malt and milk sugar, 50·44 per cent.; dextrin and other carbohydrates, 34·06 per cent.; fat, 1·40 per cent.; and mineral matter, 2·30 per cent. The preparation by itself is, of course, deficient in fat, but the food is intended to be made with milk and thus a product is obtained which contains an excellent proportion of all classes of nutritive material.

KOPA'S FOOD.

(L. KOPA AND CO., 28, GLASSHOUSE-STREET, REGENT-STREET, LONDON, W.)

We can find no dietetic novelty about this preparation. It contains cocoa and certain carbohydrates. The total nitrogen amounted to 1·65, the moisture to 10 per cent.; and the mineral matter to 4·50 per cent. The somewhat high proportion of mineral matter is due in some measure to the cocoa present.

KROOMDA CURRIES.

(MESSRS. C. DICKINSON AND CO., 30, MIDDLESEX-STREET, ALDGATE, LONDON, E.C.)

These curry preparations are certainly good and make an excellent dish. They are based on a quite simple formula of someone who has resided in India and with whom we quite agree that the curries sold in England are not at all like the original kind. Even when the curry powder may be good the average English cook knows little or nothing about preparing a satisfactorily seasoned dish with it. We have examined "curry gravy" and "prawn curry," both of which require no preparation except warming to a degree suitable for serving. In the former case, of course, any material suitable for "currying" may be added and the whole may be cooked slowly for a few minutes. We could trace no objectionable constituents in the preparations and there was no evidence of metallic contamination. The prawns in the prawn curry were somewhat tough.

EAU DE TOILETTE (LUBIN).

(PARFUMERIE LUBIN, 11, RUE ROYALE, PARIS.)

This is a very agreeable preparation for the toilet; it is fragrant, aromatic, and has a soothing effect upon the skin. According to our examination it yielded 2 per cent. of residue on evaporation which consisted largely of glycerine. It is a very pleasant and wholesome adjuvant to the toilet.

THE LANCET.

LONDON: SATURDAY, JUNE 20, 1903.

A Week of Munificence.

THE week immediately previous to Hospital Sunday was remarkable for the outburst of public benevolence directed towards the Metropolitan Hospitals. On June 7th their Majesties the KING and QUEEN attended the afternoon service at St. Paul's Cathedral. The service was, as all our readers know, in connexion with the Hospital Sunday Fund, that annual occasion being observed in the metropolitan cathedral one week before the date fixed for Hospital Sunday in other places of worship. The remarkable sum of upwards of £5000 was received at the collection which followed upon the Bishop of STEPNEY's eloquent address, a sum which we think has never before been received at any church collection made for civil needs. On June 8th the KING attended a dramatic performance at His Majesty's Theatre where Mr. TREE and his accomplished colleagues provided a splendid theatrical entertainment, the pecuniary receipts at which were handed to Guy's Hospital. An historic tragedy by Mr. ALFRED AUSTIN, the official poet laureate, and a neat adaptation from a well-known story by Mr. RUDYARD KIPLING, surely the poet laureate of the people, were played, and the exchequer of Guy's Hospital gained by £2100. On June 9th an enormous concourse of ladies and gentlemen attended a ball at Albert Hall in aid of the London Hospital, and it is anticipated that the charity will benefit to the extent of at least £4000. On June 10th a bazaar was opened at the Prince's Skating Club in aid of the Royal Free Hospital. The public, as well as the world of fashion, flocked to it and we understand that the admirable institution in the Gray's Inn-road may expect to receive a substantial addition to its funds through the strenuous endeavours of the stall-holders. This is a very remarkable group of events to have occurred on four consecutive days and shows that the public are really alive to the needs of the London hospitals—are really growing more appreciative of the work that is done in them and of the responsibilities that they discharge despite their precarious pecuniary position. It should be added that during the week over £700 were received by King Edward's Hospital Fund for London, showing that the extraordinary collections that were being made and the imminent approach of Hospital Sunday had no tendency to arrest the flow of day to day benevolence.

Leaders of society, whether leading by right of royal position or by the possession of brains, birth, or money, have all contributed to this admirable flow of munificence towards the London hospitals, and by so doing are furnishing the sociologist with a lesson that he cannot but learn while depriving the cynic of some of his cheapest sneers. The young writer, who has not yet arrived, and the older writer, who feels that he is beginning to depart, are each prone to run amok at leaders of society and to describe them as wholly given up to the pursuit of wealth and pleasure, as being meanly subservient to those who can enrich them or minister to their ambitions or feed them, but callous to the needs of those from whom they can hope to receive no advantages. Of course there are such people, but it should give pause to the writers who describe all society as composed of them—"pigs in clover" as a recent clever novel has labeled them—when the part that is being played by the KING, his Court, his blood relations, and his friends in the movement, now taking an organised shape for raising the metropolitan hospitals from their slough of debt, is considered. In addition to the various sums received in the manner that we have recorded, mention should be made of other functions taking place last week, all of which constituted an expression of public interest in hospital work and the care of the indigent sick, and with all of which members of the Royal Family were happy to associate themselves. On June 8th the PRINCESS OF WALES opened a new nurses' home in connexion with the Lying-in Hospital, Endell-street, W.C., and on the same day the Duchess of ALBANY opened the new buildings of the Kingston Nursing Association. On June 11th the KING and QUEEN made a personal visit to the London Hospital, where HIS MAJESTY inaugurated a new out-patient department, the cost of the construction of which has largely been defrayed by a splendid anonymous gift, while his Consort opened the new rooms for the treatment of the sick by the Finsen light, a method of therapy in which HER MAJESTY has already displayed practical and generous interest. On the same day the Duke of CONNAUGHT presided at the festival dinner of the Royal Blind Pension Society and PRINCESS HENRY OF BATTENBERG was present at the meeting of the Colonial Nursing Association at the Royal Hospital, Chelsea. On the last day of the week PRINCESS LOUISE (Duchess of Argyll) opened the new buildings of the Hospital for Epilepsy and Paralysis in Maida Vale. Such actions cannot fail to be of the greatest use in displaying the urgency of the needs of many of our London hospitals. By the presence of the Royal Family and their *entourage* upon these occasions a measure of publicity is secured that could be secured in no other way, and it is undoubted that the awakening of the general public conscience to their debt towards the noblest of our charities, which we consider now to be taking place, has been largely due to the acts and words of the KING and his family.

"Charity uncovereth a multitude of shins," said the flippant person in the play, alluding to the prevalence a few years ago of amateur skirt-dancing at entertainments given with benevolent object. The jibe was not intended as a compliment to the dancers and it is not unusual to hear remarks derogatory of balls, dramatic performances, and bazaars which have their *rationale* in a collection for a hospital. Why, it is asked, cannot hostesses and guests, actors and audience, enterprising stall-keepers and defrauded purchasers, alike send their cheques to the hospitals without expecting discount in the nature of some form of dissipation? The question is easily answered. The needs of a charity cannot be understood by everyone at a glance, but a bazaar, a dance, or a play needs no explanation. We, who know the value of medical charities and their sore need of support, marvel at what we are too ready to think is the callousness of those who appear to demand amusement for themselves before they will contribute to the funds of the hospitals. The public is not callous but rather uninstructed. If it were possible to make the needs of charity as clear to a thoughtless world as are the delights of a dance it is certain that many would cheerfully give their money without asking for discount in the shape of entertainment. But as it is not possible, wise people view with equanimity the accepted methods of extracting subscriptions and are grateful to the leaders of society for their labours on behalf of the sick poor.

The Summer Session of the General Medical Council.

THE summer session of the General Medical Council was a singularly uneventful one. The most important debate ranged round the unfortunately strained relations between the Council and the two great English medical corporations, and upon this subject we have already expressed our views. The rest of the session was largely taken up by the hearing of penal cases. These cases, as Sir WILLIAM TURNER foreshadowed in his opening address that they would be, were unusually numerous and in many of them the characters of the medical men in question were seriously involved. As a consequence the profession awaited with interest the methods of the General Medical Council in dealing with them, and the verdict of acquittal that most of those implicated secured, either with or without modification, has not been hailed as quite satisfactory. Let us not be understood as arguing that any particular accused medical man has been able to retain his place on the Register when he should have been removed from it; to make such a suggestion would be grossly unfair to all parties. For this reason we are unable to publish the communications that we have received, or to do more than to quote generally the impression that we know to have been created; but it is useless to disguise the fact that the sterile result of the work of the Council as a penal body has given rise to much adverse comment. Last week a correspondent, noting that certain charges of "infamous conduct in a professional respect" had been dismissed by the Council as non-proven, called attention to the stigma that has been affixed upon innocent people, and undoubtedly this is a point of view worthy of consideration; but it is merely a side-result of the circumstances. No charges are heard by the General Medical Council or preferred by either of the medical defence associations without deliberation; anonymous accusations are not attended to. We have every sympathy with those gentlemen against whom charges are brought without being sustained, but we cannot subscribe to the view that such charges are, as a rule, made in a spirit either of vindictiveness or hasty irresponsibility. The large proportion of non-proven verdicts that are found by the General Medical Council in the penal cases that come before it is due to the determination of the Council to convict only upon the most incontrovertible evidence. The members of the Council do not form a legal tribunal, they are at a disadvantage compared with a law court in taking evidence, and they possess but one punishment for all professional sins. The most shameful breach of honour or morality and the most trivial and accidental lapse from the code of professional ethics must, if punished, be punished alike by erasure from the Medical Register. The Council rightly declines to exercise its tremendous power save upon the clearest grounds, for it recognises that removal from the professional roll means the ruin of the sentenced man. Strong suspicion of a practitioner's methods may lead to a perfectly legitimate accusation of him before the General Medical Council and yet the Council may be right in acquitting him. The number of non-proven verdicts does not connote in our minds any supineness on the part of the General Medical Council; it only serves to remind us how unfortunate it is that the Medical Acts supply the Council with such clumsy machinery with which to arrange a penal code. It is to be hoped that the short Bill now before Parliament, which provides for temporary removal from the Register of the names of offenders, will soon become law so that the Council may be able to attempt in some degree to fit the punishment to the offence.

The Trinidad Epidemic.

OUR readers will doubtless recall that some weeks ago[1] we directed attention to the singular conflict of opinion that had arisen between the medical authorities of Trinidad and Barbados respecting the outbreak in the former island of an epidemic eruptive disorder which bore very marked resemblance to the outbreak of small-pox from which Barbados has recently suffered, at great loss to her trade in consequence of quarantine restrictions. It will be remembered that Mr. J. F. E. BRIDGER, who was familiar with the character of the Barbados disorder, had been sent to report on that of Trinidad and that the tenour of his report was to the effect that undoubtedly Trinidad was the seat of small-pox, which was spreading through this land mainly because its true nature was being disregarded and patients were being allowed to go about while still in an infective state. The profession in Trinidad had expressed its dissent from Mr. BRIDGER'S conclusions and appeared to regard the disease as something new, being largely influenced by the mildness of its type. We endeavoured to reconcile these conflicting opinions and pointed out that for the last few years a similar mild eruptive varioloid disease had been extending over Canada and the United States, and we considered that from the epidemiological standpoint it was highly probable that the disease, whatever it might be called, was the same in all these places. We even ventured to think that in view of the grave interests involved it might be well if an authoritative opinion by experts could be obtained by personal investigation of the Trinidad cases.

It is with a sense of relief which will be shared by all nosologists, that we are now enabled to record a distinct change in the views of the Trinidad authorities. We have before us a copy of a leaflet issued by the medical officer of health, headed "The Prevailing Epidemic: How to *Prevent* it Spreading," which compels the conviction that the disease is *now* recognised (the leaflet was issued in May) to be small-pox, although that dreaded word does not appear in its paragraphs. Moreover, a note is appended which states that its recommendations have been "submitted to the medical practitioners and have been generally approved of by them." These recommendations are drawn up clearly and concisely, and convey very plain directions as to the means to prevent contagion. There is not one of them which is not applicable to small-pox, whilst some show plainly that this is the disease which is in the minds of the authorities.

---

[1] THE LANCET, April 18th (p. 1121) and May 2nd (p. 1248), 1903.

We may briefly mention a few of the points which justify the above conclusion. The leaflet opens with the statement that "the disease is not in the air, as is generally supposed. It is catching and usually shows itself *about 14 days* after exposure to the source of infection." (The italics in this and other cited passages are ours) Here is a statement which proves that the incubation period of the Trinidad disorder is the same as that of small-pox. Like that disease it is emphasised that it spreads from person to person and the first and second recommendations deal with measures to be taken to avoid contagion from the sick, including the disinfection of bedding and clothing. No. 3 states that "the disease is catching until the spots are dry and *until all the dead skin has fallen off.*" This view was not apparently held at the time of Mr. BRIDGER'S visit, for he reported that cases were not detained in hospital then so long as is usually deemed necessary in cases of small-pox, and to this neglect he attributed much of its spread It need hardly be said that the statement strictly conforms to the general belief as to the infectivity of variola. Upon it is based the recommendation for persons who have the affection, "even in a mild form," to keep themselves apart from others and to abstain from occupations and trades which may be the means of conveyance of the contagium until the period of infectivity is passed. "Children suffering from the disease or *coming from a house affected by it* should remain away from school until they have fully recovered from it." Clearly the disease is regarded as being quite as infectious as small-pox, and it is further recommended (No. 6) that "all healthy persons should avoid coming into close contact with persons suffering from the disease."

It might be said that it does not follow that there should not be a "third disease," a "varioloid varicella" or whatever it may be termed, just as infective as variola and having a similar incubation period, to which all the foregoing recommendations are applicable. Granting this it would hardly be in accordance with scientific knowledge to find the hybrid disorder influenced by vaccination, as is now admitted to be the case. We say "now admitted" because, if we mistake not, in the earlier stages of the controversy a great point was made against the Trinidad disease being variola because it bore no relation to vaccination. Mr. BRIDGER adduced evidence to the contrary and we now find the Trinidad medical officer writing: "It has been found by experience that persons who have been *recently vaccinated* (that is, within about two years) *as a rule escape the disease,* or get it in a mild form only. *All persons not thus protected are strongly recommended to be vaccinated.*" We regard this as establishing the truth of Mr. BRIDGER'S contention that the Trinidad and Barbados outbreaks are one and the same disease, each being of the nature of small-pox. We would fain hope that the change which has obviously come over the minds of the Trinidad profession on this question will be frankly and freely admitted. It can hardly be that Trinidad, which imposed such restrictive quarantine on Barbados's commerce, is endeavouring to avoid a similar fate by declining to state openly, what is tacitly admitted, that the "prevailing epidemic" which in Paragraph 8 is termed "the pox," is the disease known throughout the world as "the small-pox."

◆

Sanitary Inspectors and their Powers.

THERE is still, it would seem, some virtue in the principle that an Englishman's house is his castle. This, at any rate, is a legitimate inference from a decision recently given by Mr. ROSE at the West London Police-court in regard to proceedings taken by the Fulham Borough Council against a person who refused admission to one of its sanitary inspectors. It was believed that ice-cream was manufactured on the premises and it was claimed on behalf of the council, in its capacity as sanitary authority, that this fact afforded sufficient ground for the inspector's entry. After adjourning the case for due deliberation Mr. ROSE came to the conclusion that under the terms of the Public Health (London) Act, 1891, there is no indiscriminate power of entry and the summons was consequently dismissed with costs.

The council, by its solicitor, relied upon Section 116 which contains the following words:—

> "If any person wilfully obstructs any member or officer of a sanitary authority or any person duly employed in the execution of this Act he shall be liable to a fine not exceeding £5"

At first sight this would appear to supply adequate powers. It is, however, a principle in the interpretation of statutes that where a matter which might be covered by general expressions is separately and specifically dealt with elsewhere it is thereby removed from the operation of the wider clause. Such separate treatment of the powers of entry is in this case to be found in Section 115 It may therefore be assumed that refusal to admit is not a wilful obstruction of the kind meant to be provided against by Section 116 and this view is strengthened by the order of the sections.

The liability to the £5 fine appears to attach only to the three cases of refusal which are mentioned in Section 115 (2) (*b*) and which are briefly:—

i. Where entry is for the purpose of carrying into effect an order of a court of summary jurisdiction.

ii. Where "it is proved that the refusal or failure is with intent to prevent the discovery of some contravention of this Act or any by-law under this Act"

iii. Cases coming under special enactments.

Of these only ii., which is therefore given verbatim, could have any applicability to the present case and it was excluded by the fact that it was not alleged that any nuisance was caused by the defendant's business.

The only machinery available is consequently that supplied by Section 115 (3) which is to the following effect:—

> "If a justice is satisfied by information on oath (*a*) that there is reasonable ground for such entry and that there has been a refusal or failure to admit to such premises, and either that reasonable notice of the intention to apply to a justice for a warrant has been given or that the giving of notice would defeat the object of the entry; or
>
> (*b*) That there is reasonable cause to believe that there is on the said premises some contravention of this Act or of any by-law under this Act, and that an application for admission or notice of an application for the warrant would defeat the object of the entry,
>
> The justice may by warrant under his hand authorise the sanitary authority or their officers or other person as the case may require to enter the premises," &c.

When action is taken in this way the penalty for obstruction becomes a fine not exceeding £20. It may well be considered whether a smaller penalty more easily obtained would not be more to the purpose.

Although no exception can well be taken from the legal standpoint to the judgment delivered by the magistrate its effects can hardly fail to be regrettable. The general public does not appreciate nice points of law and in so far as the average householder familiarises himself with this case he will probably conclude that he is justified by it in refusing admission to the sanitary inspector when he thinks proper. By acting in such a way he will materially impede the sanitary authority in its work while unconsciously laying himself open to even greater possibilities in the matter of punishment than those which he thinks he has escaped. The position of the sanitary inspector is often more than sufficiently difficult at present. He is not a welcome visitor in general and even with the weight of influence which his uniform brings to bear he meets with as many obstacles in the execution of his duty as can be interposed without his being roused to the drastic retaliation of a summons. The gusto can well be imagined with which the sweater or the purveyor of diseased meat will now shut the door in his face unless, and probably although, he comes armed with the formal warrant. Nor is the warrant always easy to get. The justice has a good deal of latitude in deciding what constitutes "reasonable ground" for entry and, as appears from the leading case of Vines *v.* North London Collegiate School, it is not enough to show that the sanitary inspector was acting honestly with a view to the discharge of his duties.

Nobody—except, perhaps, the proprietor—will question the expediency of having an ice-cream manufactory under close supervision by the sanitary authority, but if the authority has to be constantly hampered by the necessity of obtaining warrants the desired supervision can hardly be carried out in a satisfactory manner. It might be thought that in this instance assistance could be obtained from the portion of the Act devoted to the subject of unsound food. By Section 47 (1) (*b*) "any medical officer of health or sanitary inspector may at all reasonable times enter any premises and inspect and examine any article ...... deposited ...... for the purpose of sale or of preparation for sale," but it appears from Clause (6) of the same section that entry in this case also is controlled by the conditions already referred to as given in Section 115. It is possibly the result of some oversight in the drafting of the Act that the sanitary authority is so greatly restricted in its powers of entry. The matter is hardly one calling for special legislation, but when in the fulness of time the law relating to public health is brought up to date this important branch of the subject ought not to be neglected.

Annotations.

"Ne quid nimis."

THE PRINCE OF WALES ON THE RELATIONS OF THE PUBLIC AND THE MEDICAL PROFESSION.

The Prince of Wales made an admirable speech at the dinner in behalf of the Royal Medical Benevolent College last week, as our readers have been able to judge for themselves, and probably they consider, as we do, that the medical profession owes a deep debt of gratitude to His Royal Highness for his pronouncement upon the relations that should unite the public and the medical man. The intimate and trusted friend of his patients from their cradles to their graves was the picture which the Prince of Wales, as a member of the public, drew of the ideal medical man, and we are certain that this is the position to which all of us who are in family practice aspire The medical man's ministrations cannot be given merely in response to the ordinary laws of supply and demand. The grave and sacred responsibilities which he is compelled to assume beside the bed of sickness, responsibilities that may be wellnigh as important towards the patient's family as towards the patient, make it impossible that his relations with the public should be regarded merely from the point of view of mercenary service. Not a day goes by that more is not asked of the medical practitioner by some of his patients than can ever be repaid by money; and not a medical man among us but owns cheerfully that this is the circumstance of his life that brings sweetness into the round of toil. In the blackest hour of anxiety and in the brightest hour of hope the medical man is accepted as a friend whose sympathy may be assumed and whose unsparing efforts can be taken for granted. Is not this a proud position? But the practical side of the medical life must not be lost sight of, and it is undoubted that the pecuniary rewards of our professional career are not great. In particular it is exceedingly hard for the young practitioner to make any provision in the early days of practice for the future, so that early death—alas, not an uncommon thing when the work to be done is so arduous and dangerous—is apt to mean poverty (poverty, perhaps, of the direst sort) for a young widow and her children. Mainly to meet such terrible cases the benevolent side of Epsom College was founded and further support is asked for it upon the grounds indicated in the Prince of Wales's warm tribute to medical altruism. The public must always owe the medical profession a debt and they cannot pay it better than by subscribing to such an institution as Epsom College. The benevolent side of the College offers a shelter to the declining years of one set of pensioners and opportunities of a bright entry into life to another set. And whether it is the aged medical man or his widow whose infirmities preclude continuance of an unaided struggle for existence, or whether it is the little lad whose early orphanage has robbed him of his legitimate start in life—each is a legitimate object of public generosity. We are glad to see that the Prince of

Wales, in making this claim for the foundation of Epsom College in unmistakeable terms, laid stress upon the fact that the College as a whole was a highly successful public school, no more requiring public subvention than, say, Eton. It is only the charitable side that requires assistance and the assistance can be asked for with complete dignity as a right.

BABY SHOWS.

THE surest way to reach a mother's heart is through her child and commercial enterprise at Walthamstow has apparently not been slow to turn this knowledge to practical account, for we recently noticed in a morning contemporary the following paragraph: "A fat baby competition organised by a local firm of furniture dealers was one of the most popular holiday attractions at Walthamstow. Nearly 50 babies, all born in March, came to the scales which were erected in the firm's shop window. The winner tipped the beam at 16½ pounds. At the conclusion of the weighing prizes were awarded." Unfortunately, baby shows of this kind have a tragic as well as an amusing side, for the reason that they encourage the belief, which is far too generally entertained, even among the educated classes, that obesity in infants is synonymous with health. It is, however, a matter of clinical experience that a fat baby is unhealthy, with little resistance to disease, and likely to succumb on the least provocation to any of the so-called minor ailments of infancy. It is very greatly to be regretted that baby shows, if they are to be held at all, cannot be utilised for educating the laity to admire in babies those "points" which are genuinely deserving of admiration and expressive of a physiological condition, instead of acting, as they do, as direct inducements to over-feeding with foods which fatten but do not produce sound, healthy tissues. Some little time ago Mr. Rowntree in his admirable work entitled "Poverty" drew attention to the fact that the dietaries of a large proportion of the poorer classes were deficient in nitrogen-containing or proteid foods to a degree which was incompatible with the maintenance of a normal standard of health. Unfortunately, with few exceptions tissue-forming or proteid foods are expensive, while the nitrogen-free varieties such as the carbohydrates are comparatively cheap and hence there are economic reasons why the small wage-earner should, in the belief that he is laying out his money to the best advantage, provide himself and his family with foods which are quite unsuitable. The effect of this injudicious dieting is even more serious in the case of children than in the case of adult persons, for in addition to the necessity for the proteid elements of food for the repairing of tissue there is a necessity for them to satisfy the needs of growth. An examination of the dietaries of that considerable number of infants of the poorer classes who are artificially fed discloses the fact that while they are relatively starved as far as proteids and fats are concerned they are grossly overfed in respect of the carbohydrate elements, with the consequence that in addition to an unnecessarily large storage of glycogen and fat in such infants there is also a large predominance of physiologically unsound tissue approximating somewhat closely to the embryonic type, deficient in nitrogen and liable to undergo degenerative changes of the hyaline, mucoid, or carbohydrate type The appearance of these carbohydrate- or sugar-fed infants is highly characteristic. There is a curiously translucent and almost opalescent appearance of the tissues; they are hypertrophic square-headed infants and to the touch they are cold, gelatinous, and flabby, with none of the elasticity and tone which characterise the tissues of the vigorous, healthy, breast-fed infant It is these sugar-fed, gelatinous babies who receive the prizes at infant shows and are held up by their proud parents as paragons of vigorous babyhood. For this reason it is impossible to doubt the mischievous effect of fat baby shows such as that recently held at Walthamstow. Baby shows properly conducted, the prizes being awarded to those babies who manifested the largest number of really good "points" and the clearest evidence of careful management, would be a practical and fruitful means of educating the laity in the true principles of infant culture and at the same time would disabuse the minds of mothers of many of their misconceptions, and among others of their admiration for the hypertrophic pathological types which Raphael and others among the great masters have perpetuated on canvas as pleasing standards of vigorous babyhood to be copied and admired.

SIR ERNEST CASSEL'S GIFT FOR THE RELIEF OF OPHTHALMIA IN EGYPT.

Sir Ernest Cassel having given a large sum of money to the Egyptian Government for the relief of ophthalmia in Egypt it has been decided to send travelling dispensaries into the country for the relief of those sufferers who are unable to attend the already existing hospitals. There will be at first one of these dispensaries or ambulance hospitals which will have a couple of tents with beds for operation cases and for the more serious treatment of cases. This will travel about from place to, place under the direction of an ophthalmic surgeon who will have under him an Egyptian assistant surgeon. If the experiment is successful the number of dispensaries will be increased. [illegible] by the Egyptian G[illegible] the enterprise with [illegible] ophthalmic dispensaries in Egypt." Mr. MacCallan was formerly senior house surgeon at the Royal London Ophthalmic Hospital (Moorfields) and at the present time holds the post of chief clinical assistant at the hospital. He will leave for Egypt immediately and has clearly the necessary qualifications to start the quaint experiment upon a sound basis. But what will be regarded as a sufficient measure of success to justify the making of further experiments, and who is to judge what is a success and what is a failure?

PARALYSIS AGITANS.

A VALUABLE "symposium" on paralysis agitans appears in the *New York Medical Journal* of May 2nd, and among the contributors are Dr. Joseph Collins, Professor M. Allen Starr, and Dr. Bernard Sachs. The facts observed and collected cover a very extensive field and refer mainly to the etiology, pathology, and treatment of this affection in their latest developments. Dr. Collins states in his paper that among 50 cases recently under his care 34 were males and 16 were females or 68 per cent. and 32 per cent respectively. The average age at which the disease developed was 51 years. The youngest patient was 32 years of age and the oldest 72. He found paralysis agitans to be frequent among persons of Celtic descent and rare among the Hebrews. There was a history of neuropathic heredity in 13 of the cases or 26 per cent. and a history of paralysis agitans in the parents or uncles in six cases Syphilis and alcohol were conspicuous by their absence as etiological factors. Worry and anxiety were traceable in seven cases and injury was assigned as a cause in the same number of cases. Dr. Collins stated his belief that "paralysis agitans was a disease of early senility, occurring as the reward of virtue." Professor Starr stated that a hereditary predisposition to the disease was met with in about 4 or 5 per cent. of cases, but that anxiety and injury appeared to him to bear a distinct etiological relation to paralysis agitans. He had never seen a patient absolutely cured of and tuberculous parents often showed tendencies to bodily mal-development and mental instability. Syphilitic children were dull and torpid, whereas tuberculous children—those of tuberculous diathesis but as yet free from tuberculous infection—were precocious and hyper-excitable. Parental tuberculosis, therefore, had a definite specific effect upon the offspring. Professor Adami pointed out that by the application of the graphic and mathematical methods devised by Professor Karl Pearson[1] it was possible to estimate the "expectancy of life" of candidates for life assurance who though themselves free from tuberculosis were inheritors of a tuberculous diathesis. There were certain hereditary conditions such as albinism, sexdigitism, and colour-blindness which did not affect longevity, but, on the other hand, hæmophilia did. A recognised "bleeder" was a distinctly unsafe life and must be shunned by insurance companies, for at any moment a trivial accident was liable to lead to a fatal hæmorrhage. Professor Adami concluded by referring to cases of offspring showing extreme variation from the parental type or so-called "sports." Such "sports" tended to perpetuate themselves in subsequent generations, but they were deficient in vitality and length of life. They had a special liability to succumb to disease and hence such individuals were to be accepted with caution for life assurance.

THE METROPOLITAN WATER-SUPPLY.

THE Water Examiner has lately issued his report on the metropolitan water-supply for the month of April. During the time under review the Thames water at Hampton, Molesey, and Sunbury was in good condition from the third to the twenty-ninth days. On April 1st, 2nd, and 30th it was of indifferent quality and on the last of these days the intake of the Chelsea Waterworks Company was closed. It would have been of interest to have been told whether on the same day the Thames river water was taken by the East London Waterworks Company and, as usual, filtered without undergoing the preliminary process of sedimentation. A full analysis of such water might prove of more use than the whole of the rest of the Water Examiner's report put together. In connexion with the Thames supply of the East London Waterworks Company it is of interest to note that the daily average amount of water derived during the month of April from the Hanworth "springs" was no more than 605,000 gallons, which is much below the amount usually obtained. The height of the Thames river level varied from a point one foot four inches above to one seven inches below the average summer level. At Molesey the total rainfall during the month amounted to 1·76 inches. The average daily supply delivered from the Thames was 111,394,207 gallons, from the Lee 48,223,407 gallons, from "springs" and wells 41,626,330 gallons, and from the Hampstead and Highgate ponds 258,158 gallons. The total daily average was 201,502,102 gallons for a population estimated at 6,484,238 and this represents a daily consumption per head of 31·08 gallons. The companies which do not profess to give constant service to their customers are the Kent, the New River, the Southwark and Vauxhall, and the Lambeth, and these give a constant supply to 99·8, 96·6, 95·4, and 78·5 per cent. of their clients respectively. The proportions of brown tint observed in a two-foot tube varied from three to 24 degrees of the standard in use. The water of the West Middlesex Company exhibited the deepest average tint of brown. Of late the quality of the water supplied by this company has deteriorated in comparison with that distributed by some of the other metropolitan companies and it is time that the attention of the directors should be called to the matter. Dr. T. E. Thorpe, C.B., F.R.S., the chemist employed on behalf of the Local Government Board, reports that the one sample of the water supplied by each of the metropolitan companies on April 23rd was fully examined. The results of these analyses show that the relative amount of the organic impurity of these specimens may be numerically represented as follows: Kent, 8; New River, 17; Southwark and Vauxhall, 24; Lambeth, 30; East London, 34; Grand Junction, 40; Chelsea, 41; and West Middlesex, 46 The water supplied by the New River Company was, as usual, of very good quality and that supplied by the Kent Company was excellent but hard.

THE ELEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE above-mentioned Congress will be held at Brussels from Sept. 2nd to 8th of the current year. The President is M. Beco, secretary-general to the Minister of Agriculture and chief of the Brussels Sanitary Department The general secretary is Dr. Putzeys, professor of the Faculty of Medicine of the University of Liège, whose address is No 1, Rue Forgeur, Liège. The hygiene division of the Congress is divided into seven sections—viz., (1) bacteriology; (2) the hygiene of foods, including chemistry and veterinary matters; (3) sanitary technology, including engineering and architecture with reference to hygiene; (4) the hygiene of trades and professions; (5) the hygiene of railways, shipping, and other methods of transport; (6) administrative hygiene, including the prevention of transmissible diseases, workmen's dwellings, and infantile hygiene; and (7) colonial hygiene The Belgian State railways give facilities and fares at reduced prices. Other information can be obtained from the general secretary, Dr. Putzeys.

THE NEW BUILDINGS OF THE GLASGOW ROYAL INFIRMARY.

THERE has been for some time under consideration a scheme for the reconstruction of the Royal Infirmary, Glasgow, but it appears from a correspondence just published that the efforts in this direction of the controlling body of the infirmary have not met with the approval of at least one section of the inhabitants of the city. In January, 1900, ten architects were invited to send in suggestions for the new buildings which were to be erected and Sir Rowand Anderson was appointed assessor. After careful examination that gentleman recommended one of the designs but a committee of the managers disregarded his verdict and chose certain plans which he had not even included among the first four. With regard to these proceedings the local Institute of Architects has been much exercised in mind. Its secretary wrote on its behalf to protest against the selection and has continued to protest until at last the committee has declined to discuss the matter further. Objection is taken by the institute to what is regarded as the unfairness of departing from the ruling of the assessor, since it may be assumed that there was an implied condition that his advice would be acted upon unless there were good reason to the contrary. It is maintained that the accepted plans are in many vital particulars inadequate and out of date and that the infirmary, if erected in pursuance of them, will not conform to the most modern standards of design in this class of building More than this, it is held that the plans adopted will result in the production of a structure dwarfing and irretrievably injuring the external appearance of the adjacent Cathedral. The institute has therefore requested that the whole of the designs should be submitted to one or more hospital experts before anything more is done and having, apparently, the courage of its convictions, has offered, if its contention is not supported, to defray the cost of such submission. For the committee it is stated that the plans now being followed are perfectly suitable ones and were in the first instance excluded by the assessor chiefly on account of his views as to the style of architecture and the general elevation, points upon which the managers consider themselves quite able to form an opinion. This may be a correct attitude to assume. We do not suggest that in cases of this kind the judgment of an assessor must be invariably deferred to. He is only a means to an end and if that end can be attained more satisfactorily in some other way there is no cause for complaint. We are, however, quite in accord with the Glasgow architects in desiring that the canons of art shall be respected so far as is practicable. Without further evidence on the merits of the case it is impossible for us to speak with certainty, but it seems to us that the answer which the institute has received is hardly convincing and we trust that the managers of the infirmary will see fit to allay the misgivings which the publication of their intentions must raise in the minds of many. It ought to be feasible to erect hospital buildings without sacrificing elegance to utility and where, as here, the appearance of one of our all too few public monuments is concerned some concession may appropriately be made to popular sentiment.

---

RAILWAYS AND THEIR SANITARY ACCOMMODATION.

A DECISION was given by Mr. Curtis Bennett on June 15th which will no doubt be followed by an appeal and the settlement of an important point of law in connexion with sanitary matters. The Metropolitan Railway Company, constructing sanitary works at their station at Finchley-road, contended that they had power to do so under their private Act of Parliament and such other Acts affecting railway companies without giving notice to the local sanitary authority and receiving its approval of the work to be done. On the other side, a summons having been taken out against the contractor employed, it was contended that by-laws of the London County Council had been infringed and that these applied to the premises occupied by the railway company as well as to those for which private individuals were responsible Mr. Curtis Bennett, after consulting the numerous Acts and sections bearing upon the matter, decided in favour of the complainants and inflicted a fine amounting, with costs, to £11 6*s*. That the matter is of importance may be gathered from an observation of the learned magistrate who said, in delivering his decision, that if the contention of the defendants was correct any insanitary place on a railway, even if it affected a whole neighbourhood, could only be dealt with by the costly process of indictment.

INSANITY AND RACIAL FECUNDITY.

AN interesting article on insanity in relation to racial fecundity is contributed by Dr. John Macpherson, Commissioner in Lunacy for Scotland, to the issue of the *Edinburgh Medical Journal* for May. The article is based mainly on a study of the vital statistics of Ireland considered in reference to the decrease of the population and the increase of insanity in that country, but the general conclusions reached are, adds Dr. Macpherson, applicable also to England and Scotland. The increase of insanity in Ireland during the past half-century is undoubted The proportion of lunatics and idiots under the official cognisance of the Inspectors in Lunacy in Ireland in 1851 was 1 to 657 of the population, in 1861 it was 1 to 411, and in 1871 it was 1 to 328. Since then the proportion of the insane to the rest of the population has continued steadily to rise, the figures being 1 to 281 in 1881, 1 to 222 in 1891, and 1 to 178 in 1901. The actual numbers of all lunatic and idiots under official cognisance in Ireland were 23,187 in 1881, 36,133 in 1891, and 44,884 in 1901, while the population for the corresponding years has been 5,174,800, 4,704,700, and 4,453,600 respectively. This steady decrease in the population is due, as Dr. Macpherson points out, to emigration. Thus, during the 20 years ending March 31st, 1901, 1,199,100 persons of both sexes emigrated from Ireland, the number of female emigrants very slightly exceeding that of the males. That with a diminishing population there should occur an absolute as well as a relative increase in the number of insane persons is, adds Dr. Macpherson, a very striking phenomenon. The depletion of the population by emigration chiefly affects its sexually efficient units—persons of both sexes between the ages of 15 and 55 years, since the vast majority of the emigrants are young adults or persons below the age of 55 years. One result of this depletion is, argues Dr. Macpherson, that the marriage-rate is lowered in the country thus depleted of its marriageable young adults. From a careful comparison of the official statistics of emigration and of marriage as regards the various counties of Ireland the broad conclusion is reached that "the prominent factor in the vital statistics of Ireland is the association of emigration with a declining marriage-rate." Dr. Macpherson then proceeds to point out that there is a correlation between "maximum fertility," or fecundity, and the "normal healthy racial type." The emigration of so many units of the latter tends to leave behind a less fertile stock, for it is the artisan and working classes which possess the maximum of fertility and which constitute the main body of emigrants. It is further shown from a study and comparison of various statistics on fertility and on the liability to disease of large communities that a high degree of fertility is, in accordance with general biological laws, accompanied by a low ratio of morbidity (liability to disease including mental disease) The depletion of the more fertile stock tends to leave behind a less fertile stock which, however, is more prone to develop insanity as it is to suffer from other diseases. Hence the increase of insanity is more rapid absolutely in Ireland than in England or in Scotland where the effects of emigration are less felt. Dr. Macpherson concludes that this general biological law does not, of course, exclude other factors in the production of insanity—factors which are as applicable to the rest of the United Kingdom as to Ireland itself.

EMBLEMS OF THE MEDICAL PROFESSION IN JAPAN.

THE June number of *Man*, a journal published under the direction of the Anthropological Institute of Great Britain and Ireland, contains an article by Mr. E. S. Hartland, F.S A., on two Japanese *boku-to*, or emblems of the medical profession. These objects, of which photographic representations are given, were wooden swords worn by medical practitioners in Japan before the revolution of the last century which displaced so many of the old customs of the country. A man of rank was formerly entitled in Japan, as elsewhere, to wear a sword; indeed, in Japan he was entitled to wear two swords. The retainers of a Daimio or feudal lord also wore swords. The medical men's swords were generally of a somewhat fanciful description and were made in many forms; some contained lancets, others contained knives for cutting herbs, but the majority were quite plain. One of the objects now described and figured is in the shape of a large bean-pod. Its bean like curvature approximates to that of a Japanese sword. It is 44 centimetres (17½ inches) in length and of a nearly uniform circumference of 11 centimetres or thereabouts It is made of some fairly hard wood which takes a polish and it is carved to indicate seven seeds inside Wrapped around it is a silken cord by which it was attached to the girdle. Together with this cord it weighs six and three-quarter ounces avoirdupois On the side there are represented in lacquer a grasshopper and another large insect. On the other side are similarly represented a wasp, a small fly somewhat like the common house fly, and apparently a small beetle. The other *boku-to* is more interesting. It is a rough piece of willow, 45 centimetres long and broader at the bottom than the top. Japanese characters meaning *Spider-boat* have been deeply cut upon it. At a distance of nine centimetres from the top it is pierced with a hole three and a half centimetres long which has been utilised to attach a flat cord or tape and toggle for convenience of holding it in the girdle. The cord is of a pale red colour, now a little faded. The *boku-to*, cord, and toggle weigh together under four and a half ounces avoirdupois. The two specimens now described were bought at Atami in Japan a few months ago.

"OPTICIANS" AND SPECTACLE PRESCRIBING.

WE have received two long letters from Mr. J. Aitchison and Mr. L. Laurance as rejoinders to our leading article upon their former communications which appeared in THE LANCET of June 6th, p. 1617. We thought it fair and courteous to give these gentlemen a hearing on that occasion, but we see no reason for permitting them to continue a controversy on which, in our opinion, there is nothing new to be said. The simple facts are that the eyes are organs in which mere faults of shape and alterations of function incidental to advancing life are frequently complicated by physiological defects and pathological changes of a serious character. The knowledge of the medical practitioner covers the whole range of the resulting phenomena; the knowledge of the "optician" at the very best covers only a small and comparatively unimportant portion of them. In these circumstances the claim of the "optician" to be a skilled adviser in matters appertaining to vision appears to us not only to be one which it is impossible to sustain, but one which cannot fail in a certain, and perhaps considerable, proportion of cases to entail disaster upon those who are misled by it. The action of the prescribing "optician" is precisely on all fours with that of the prescribing druggist. If it be the pleasure of the public to be deceived the public must suffer, and in the meanwhile we have discharged our duty by giving expression to the facts of the case.

THE NEW UNIVERSITY OF LONDON.

Sir Arthur W. Rücker, Principal of the University of London, in the course of his remarks on the occasion of the distribution of prizes at St. Thomas's Hospital Medical School on June 11th, observed that the growing closeness of the relations between the great medical schools and the University of London should be emphasised as far as possible. In the reorganised University of London they possessed machinery of the most extraordinary flexibility, though the actual government of the University was really very complicated because the democratic nature of its organisation rendered it necessary that an enormous number of people should be consulted. All the medical schools connected with the University of London had a share and voice in determining the way in which the subjects in which they were interested were taught. The University could single out one teacher in an institution in London and recognise him and him alone, or it might, as University College hoped it would, take over the entire control of an institution as a whole. In broad terms, the relation of the great medical schools to the University would be something like the relation that existed between the colleges of Oxford and Cambridge to those universities. They would be absolutely independent but would be represented on the governing body of the University and in that manner would help to formulate the conditions under which diplomas would be granted. One of the principal features of the University of London would be that it would become a great centre for post-graduate work. Within the last year the University had held out its hand to the graduates of other universities in a way it had never done before. The University of London had entered into the fraternity of learning and would make it as easy as possible for those people who had passed competent tests elsewhere to make such use as they pleased of the University. The new plan only came into operation on Oct. 1st last and there were already on the books of the University 206 graduates of other universities who in such a short space of time had taken advantage of the new door that had been opened to them. Of those among that number who had entered as internal students only two or three were going in for medicine and Sir Arthur Rücker wished to point out that a graduate from another university desiring to finish his medical education in the University of London derived certain advantages if he entered as an internal student. He had the privilege, provided that he produced the proper certificates, of being able to cut down his time from five years to three. In some of the great medical schools the authorities believed that they should be relieved of the burden of teaching such subjects as chemistry, physics, and physiology which could be taught at a distance from a hospital. The Senate of the University of London had approved of a plan sent up by the Faculty of Medicine for the establishment of an institution where those subjects could be taught and if the funds could be found a site could be obtained close to the University of London.

SOME INTERESTING FACTS REGARDING THE PURIFYING EFFECT ON THE AIR OF THE RECENT RAIN.

WE have often pointed out that the passage of raindrops through the air not only purifies the air but imparts a freshening effect to it, due possibly to an oxidising action and perhaps to the formation of peroxide of hydrogen. Everyone is familiar with the "clean" smell of the air after a rainstorm. According to this view the air of the county of London must have sustained a very thorough scouring during the remarkably continuous rainfall which began on Saturday, June 13th. There was very little movement in the air and an opportunity was thus afforded of collecting the water for analysis, the results of which would represent some at any rate of the impurities washed out of the air immediately over this area. The following were the results obtained with raindrops caught in the neighbourhood of the Strand on Monday, June 15th:—

	Grains per gallon
Total solid matters	9·100
Common salt	0·800
Ammonium sulphate	0·652
Organic ammonia	0·011
Soot and suspended matters	5·000
Nitrates	None.
Nitrites	Very distinct.

The amount of ammonia in the form of sulphate is remarkable and, of course, its chief origin is the combustion of coal. The nitrites with traces of ammonia are due to electrical discharge in the atmosphere. These results when worked out with the total rainfall give some remarkable figures. Taking the rainfall as 3·8 inches in five days (though a higher figure than that has been returned by some observers) we arrive at the calculation, based on each inch representing 22,622 gallons of water falling upon one acre and the London county acreage as 74,839, that no less than 6,437,229,860 gallons of water were poured over this area. And according to the above results of the analysis of the rain-water this enormous volume represents the washing out of no less than 3738 tons of solid impurities, of which 330 tons consisted of common salt, 267 tons of sulphate of ammonia, and 2000 tons of soot and suspended matters. Regarding the combustion of one ton of coal to produce 20 pounds of ammonium sulphate (a very fair average) the quantity of coal represented by the ammonium sulphate washed out by the storm would be 29,904 tons. It need hardly be added that the purification is not only, as is here shown, mechanical, physical, and chemical, but bacteriological also.

THE DISTRIBUTION OF PLAGUE.

As regards Hong-Kong, a telegram from the Governor received at the Colonial Office on June 11th states that for the week ending June 6th there were 136 cases of plague, of which 4 occurred in Europeans. During the same period there were 94 deaths from the disease. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on June 12th states that for the week ending June 11th there were 2 fatal cases of plague.

CHILDREN UNDER THE POOR-LAW.

DURING the course of a discussion on a vote for the Local Government Board which took place in Committee of Supply on June 11th several Members of the House of Commons expressed their views as to the best manner of dealing with pauper children. The general effect was the familiar one of darkening counsel and Mr. T. W. Russell's conclusion that the problem could only be settled by using all the methods—schools of moderate size, village communities, boarding out, and scattered homes—may be taken as summing up all that the debate had of value. As to the desirability of getting the children out of the workhouse there is no dispute; it is chiefly in regard to the relative merits of boarding out and of erecting schools that differences of opinion arise. For boarding out there is much to be said. Since the children are scattered there is little risk of their being involved in epidemics, especially of ophthalmia, such as are common in the schools. School life is wearisome, because as the children have no other homes there are not for them those breaks in the monotony which holidays supply. Moreover, the conditions are so different from those of ordinary life that the children leave the institutions with little conception of how to spend to the best advantage their limited earnings and, in the case of girls, without any aptitude for domestic service, which is practically the only opening for them. In these respects the boarding-out system is much more satisfactory and there is the further consideration that on leaving a home the child is usually able to maintain friendly relations with the foster-parents and has, therefore, a place of resort in emergencies, while it is possible for anyone who has come to be interested in the child's welfare to exercise some degree of control over him or her for years afterwards. One of the most successful centres for boarding out has been that of Calverton (Bucks) authorised in 1871. Here the Rev. W. P. Trevelyan has devoted himself to the care of the children with the result that of 92 boys and 112 girls who have passed through his hands during 31 years only five have been lost sight of, while the great majority have been converted into useful members of society. The schools, however, have their value. Experience has shown the difficulty of properly supervising the children boarded out and in the case of those who are mentally deficient and consequ [illegible] troublesome several instances of cruel treatment [illegible] recorded. Again, boarding out is hardly practicable e [illegible] with orphan or deserted children owing to the risk of [illegible]ference from relatives. On June 12th and 13th, at the Church House, Westminster, representatives of the various London Poor-law schools gave a series of gymnastic displays arranged by two of the organisers of the London School Board. The children seemed to be happy and healthy and their dress and bearing reflected credit upon those in charge of them. On the first day Mr. Grant Lawson presided and quoted certain figures to show that the schools were doing good work. He mentioned that of 3187 girls traced only 262 were reported by their mistresses to be unfit for their duties, while of 1275 boys only 43 had been described as unsatisfactory. The position is therefore not one of rivalry between two systems and the matter at issue is merely the selection of suitable cases to be dealt with under each.

THE Workhouse Nursing Association will hold a conference at 10, Great George-street, Westminster, London, S.W., on Monday, June 29th, at 3 P.M., to discuss the report of the Departmental Committee on Nursing appointed by the President of the Local Government Board. The Right Hon. J. G. Talbot, M.P., will preside.

THE Cavendish Lecture of the West London Medico-Chirurgical Society will be delivered on Friday, June 26th, in the town hall, Hammersmith, at 8.30 P.M., by Professor T. Clifford Allbutt, the subject being *Disease* of the Ascending Aorta, and not Atheroma as previously announced.

THE autumn congress of the Sanitary Institute will be held at Bradford from July 7th to 11th inclusive. Information can be obtained from the secretary, Mr. E. White Wallis, the Sanitary Institute, Margaret-street, London, W.

VISIT OF THE KING AND QUEEN TO THE LONDON HOSPITAL.

HIS MAJESTY THE KING, accompanied by Her Majesty Queen Alexandra, visited the London Hospital on June 11th on the occasion of the opening of the new out-patients' department by the King. Their Majesties were received at the vestibule of the building by the President of the hospital, the Duke of Cambridge; the chairman of the hospital, the Hon. Sydney Holland; the senior physician, Dr. Stephen Mackenzie; the senior surgeon, Mr. C. W. Mansell Moullin; and Sir Frederick Treves, consulting surgeon. Their Majesties were then conducted to the reception room where they were presented with an address from the mayor, aldermen, and councillors of the borough of Stepney, and [illegible] accepted the King and Queen [illegible] ut-patients where [illegible] On the entrance [illegible] entor called upon those present for cheers for their Majesties, which was heartily responded to. After the King and Queen had been conducted to a raised and decorated platform the first verse of the National Anthem was sung and then prayers were offered by the Bishop of London and the company sang the hymn, "O God, our help in ages past." The Duke of Cambridge, attended by [illegible] welcomed their Majesties to the [illegible] Iolland, accompanied by M [illegible] iced and presented the add [illegible] agement which was read by [illegible] ckenzie, accompanied by hi [illegible] ves and Mr. Mansell Moullin, next came forward and presented the following address which was read by Dr. Mackenzie:—

> May it please Your Maje [illegible] connecting the consulting staff, Mr. Ma [illegible] I as senior physician, speaking [illegible]

His Majesty then received his reply from Mr. Akers-Douglas, M.P., and read it in a clear voice so that every word was heard by those present. He referred to the satisfaction of the Queen that the Finsen light cure for lupus had been introduced into this country. He thanked the anonymous donor for the £25,000 towards the cost of the new building. His Majesty then said that before declaring the building open he wished to record his deep feeling of gratitude to the London Hospital which at the time of his severe illness provided him "with so distinguished a surgeon as Sir Frederick Treves, with an anæsthetist in Dr. Hewitt, and with two such nurses, Nurse Haines and Nurse Tarr, whose unceasing attention" he could not sufficiently praise.

The King and Queen then proceeded on a tour of inspection through the x-ray, the electro-therapeutic, the lupus, the ophthalmic, and the aural departments. In the course of their progress the Queen pinned badges upon the breasts of 15 nurses who had proceeded to the war in South Africa from the London Hospital. During this ceremony Her Majesty said that she was confident when she sent the nurses out to the war that they would do honour to the training they had received from Miss Lückes at the hospital. In the x-ray department their Majesties spent some time and after they had had their hands radiographed the apartment was darkened and Dr. R. Morton exhibited an atom of radium which sent its rays through several penny-pieces. In the department for the treatment of lupus by the Finsen light the Queen went through the ceremony of declaring the rooms open and hoped that all the patients who left would be cured and would "give a blessing to her great countryman, Professor Finsen, who through hard work and perseverance had made that wonderful discovery." Much attention was paid by their Majesties to the case of a patient who had travelled from Turkey and after a year's treatment was nearly cured. In the ophthalmic department a patient with colour-blindness attracted the notice of the King and Queen and their Majesties were shown cases of cataract. In the aural department the Royal visitors were shown three girls, triplets, who were born deaf and dumb but whose speech and hearing had been restored to them. Some little time was spent in this part of the tour of inspection and their Majesties did not proceed on their journey until the method of examining the tympanum had been demonstrated to them and they had themselves looked down an aural speculum. Their Majesties then returned to the vestibule, passing through the operating theatres on their way, where a Crimean veteran who was awaiting surgical treatment was recognised by one of the King's suite and the Royal party delayed their departure to say a few kindly words to the sufferer. The King and Queen then left the hospital amid loud cheers and proceeded on their way to the Mansion House to take tea with the Lord Mayor and Lady Mayoress.

We append a few particulars of the new out-patients' department.

The building is entered from Oxford-street through a large vestibu
capable of seating 200 patients, in which are the registration and tick
offic l cases receive th
ticke pacious waiting h
havi At the east end
the rooms forming
surg geon's room, clini
assistant's room, an operating room with a recovery room adjoini
two examining rooms, and in both male and female sides there
waiting rooms for old and new cases with separate surgical dress
rooms. At the west end is situated the medical department. This
also two suites of rooms and each consists of physician's room, clini
assistant's room, two examining rooms, and waiting rooms for both
and new cases for each sex. A refreshment bar is attached to
waiting hall for the sale to the patients of light refreshments
nominal prices. Drinking fountains are provided both in waiting h
and vestibule.

The general arrangement of the plan of the building insures th
the patients after entering at Oxford-street are sorted and the
proceed through the department in which their case is dealt with, an
after obtaining their medicine leave by the exits into Green-stre
without crossing the progress of other patients. This arrangeme
naturally facilitates the management of the great numbers whic
have to be dealt with by the officials. There are two priva
entrances from the street for the use of the staff and the official
This out-patients' department is connected with the west wing
the hospital by means of a subway which is constructed und
Turner-street. On the first floor are situated the aural, dent
obstetric and massage departments, each of which is comple
in itself, having the necessary consulting, operating, and waitin
rooms. The second floor is devoted to the ophthalmic, photograph
and electrical departments. The lupus department is also on this flo
and contains the Finsen lamp which Her Majesty presented to th
hospital together with several other lamps. There are separate roo
for the surgical dressing of wounds, medical officers, and nurses. T
motor-generators and other apparatus for the transforming of the electr
current to supply this department are situated in a room on the ro
above. The basement contains a large laboratory department, full
equipped for the manufacture of medicine, pills, lozenges, and sod
water, and has large stores for drugs, dressings, and other necessar
for medical and surgical treatment. The bath department consists
medicated and Turkish baths with the necessary dressing and waitin
rooms, and is also in the basement together with the boilers, isolatio
rooms and accommodation for students, dispensers, porters, and othe
officials

The whole building is of fire-proof construction and the floo

THE ANNUAL DINNER OF THE INDIAN MEDICAL SERVICE.

THIS dinner took place at the Café Monico on June 11th, Surgeon-General Sir JOSEPH FAYRER, Bart., K.C.S.I., F.R.S., occupying the chair, in the absence of Surgeon-General Sir Annesley De Renzy, K.C.B., who through domestic affliction was prevented from presiding.

After the usual toasts had been given from the chair and had been duly honoured Sir JOSEPH FAYRER proposed "The Indian Medical Service." He observed that on a previous occasion he had given a brief *résumé* of the work of some of the most distinguished medical officers belonging to the service, men whose names are and ever will be associated with its greatness as exemplars of all that has raised it to its present position. He thought that they had good reason for maintaining confidence in the prospects of the service and [illegible] pirit of scientific research was [illegible] He coupled with the toast the [illegible] K.C.S.I., and Surgeon-General A. Scott Reid.

Sir WILLIAM HOOPER having briefly replied,

Surgeon-General REID, after some humorous remarks, said he wished to speak on certain causes of dissatisfaction which existed in the Indian Medical Service and he would only refer to those which had been in operation since he entered the service, that is to say, during the last 31 years. He would first take up those which principally affected the military side. The first source of discontent was, he thought, the amalgamation, in 1880, of the military medical administration. He did not deny that this change might have been inevitable and to the advantage of the State, but it certainly was not popular with the Indian Medical Service. The immediate effect of the change was, of course, to diminish the number of administrative appointments and to throw back the average length of service for promotion to that grade by at least three years, thus practically cutting off all men who entered the department after the age of 25 years from any hope of attaining such an altitude. But it did more than that—it threw all medical officers in military employ out of touch with the head of their service who ceased to have more personal or official relations with them than the Mad Mullah of Somaliland. It was true that the order effecting the measure did not positively exclude the Indian Medical Service from the highest appointment, but Surgeon-General Reid thought he would be a bold and over-sanguine Indian medical officer who hoped ever to become Principal Medical Officer of His Majesty's forces in India. The blow was softened to some extent by conferring on sanitary commissioners of provinces the pay and status of administrative officers, but this privilege was in time withdrawn and in its turn partly compensated by the grant of four extra £100 retiring pensions, a concession which had, however, for some years been abolished for those entering the service. Surgeon-General Reid added that having said so much he must guard himself against the suspicion of any unfriendly feelings towards their sister service. He had many friends in it and his three staff officers belonged to the Royal Army Medical Corps. He could not be served by better. The matter was a purely impersonal one. A further cause of dissatisfaction was the want of suitable appointments for senior medical officers. As far as he could see the introduction of the station hospital system was the only remedy, but when he said this he freely admitted that if put to the vote the majority of officers in the service would go against it—and why? Simply because the majority were young. The introduction of the station hospital system would, in his opinion, be greatly to the advantage of the service and would undoubtedly establish a considerable asset of economy and efficiency in the accounts of the State. A cause of disappointment among young medical officers of the Indian Medical Service was the backward condition of hospitals for native troops. There had been some improvement since he entered the service but not in keeping with the advance in civil hospitals. Their equipment was meagre and the resources for treating disease were very crude. Of skilled nursing there was none and the range of dieting was very limited. Finally, as regarded the military side, he referred to the frequent transfers among junior officers. This was a very acute evil and he supposed could only be remedied by increase of establishment. He knew of several who for the first year or two had had as many moves as months and who during that period had had no opportunity of studying for, or passing in, the lower standard examination. This was hard on them. They were put to endless expense and for the time remained ineligible for charge pay. In his opinion an officer of the Indian Medical Service on arrival should be left undisturbed at the headquarters of his district until he had had a fair opportunity—say, for six months—of qualifying in the vernacular and he should draw the pay of any charge in which, owing to the exigencies of the service, he might be placed during that period. Surgeon-General Reid said he would turn next to the civil side. Although the Indian Medical Service was considered to be primarily a military one and the services of its members were only lent to the civil department, there was no doubt that in former times at least employment in the latter formed the main attraction and object of ambition to candidates. This factor was, however, he feared, not such a powerful one now, for during his tour as administrative medical officer of the Central Provinces several civil surgeons there, and some of them permanent, returned to military employ of their own accord, while since going to the Punjab command as principal medical officer about the same number who had registered their names for civil employment refused the chance when it was offered to them. He presumed that they considered that any slight advantage they might gain with regard to pay would be more than counterbalanced by having to serve in small and remote stations with little prospect of bettering themselves. Another cause—but here he feared he was skating on thin ice—which had rendered civil employment less popular lay in the restrictions which the Government had been pleased to place on the acceptance of fees for professional services rendered to chiefs, native noblemen, and men of position. From the days of Clive, when the channels for the augmentation of official incomes were closed to other Government servants, whose pay was, however, raised to com[illegible] As far as he knew the privilege had never been abused. Finally, viewing the service as a whole he considered that the pay throughout and some of the positions required recasting if they were to retain the class of men who formerly entered its ranks. To begin at the top, he was of opinion that the Director-General should have the rank (as in the Royal Army Medical Corps) and the pay of a lieutenant-general; also that he should be a secretary to the Government of Indi[illegible] Member of Council. It [illegible] head of an important [illegible] obliged to submit his proposals through, and subject them to the criticism of, men of perhaps two-thirds of his length of service and not that proportion of special knowledge of the subject that was being dealt with. His pay at present was only that of a second-class commissioner of a division and their late Director-General, Robert Harvey, than whom the Government of India never had a more loyal servant, or the department a truer friend, had told him that but for his private income he could not properly have supported the position. Surgeon-General Reid conceived that the head of their service should be able to hold his own socially among others in analogous appointments and, above all, that he should be enabled to receive and to entertain all the members of his own service who called on him. In this way—he was thinking more of the young men—the Director-General would have a greater opportunity than through other channels of forming their acquaintance, of gaining their confidence, of gauging their characters, and of encouraging and stimulating them in their careers. Similarly, with regard to inspector-generals of civil hospitals, they too ought to be secretaries and members of the provincial council. Surgeon-General Reid concluded his speech by referring to the paucity of honours and rewards given in recognition of distinguished but purely professional work.

The toast of "The Visitors" was proposed by Lieutenant-Colonel A. CROMBIE, C.B., and responded to by Sir WILLIAM S. CHURCH.

The evening concluded with an acknowledgment of the services of Lieutenant-Colonel P. J. Freyer who acted as secretary of the dinner and who, in acknowledging the compliment, referred to their loss by death of Surgeon-General W. R. Rice, and the absence of Dr. W. S. Playfair who presided on the last occasion.

The following members were present:—

Surgeon-Generals: G. Bainbridge, W. W. Beatson, Sir J. Fayrer, Bart., K.C.S.I., F.R.S., Sir W. R. Hooper, K.C.S.I., A. Scott Reid, C. Sibthorpe, C.B., and P. W. Sutherland.

Colonels: G. H. Banks, W. E. Cates, H. Cayley, C.M.G., D. Hughes, B. Williamson, and W. S. G. Wynne.

Lieutenant-Colonels: M. L. Bartholomeusz, G. H. Bull, A. Crombie, C.B., H. H. Dimmock, J. Duke, A. Duncan, P. J. Freyer, G. S. Griffiths, P. de H. Haig, W. H. Henderson, J. Lewtas, J. B. Lyon, C.I.E., D. P. MacDonald, D. Ff. Mullen, J. O'Brien, J. Parker, G. S. Sutherland, W. H. Thornhill, J. F. Tuohy, A. H. Williams, and E. W. Young.

Majors: E. H. Brown, W. J. Buchanan, W. S. Caldwell, P. Carr-White, B. B. Grayfoot, A. G. Hendley, H. Hendley, J. G. Hojel, J. Jackson, M. A. Ker, C. H. L. Meyer, L. Rogers, and B. J. Singh.

Captains: H. Boulton, S. H. Burnett, A. W. F. King, W. Murphy, J. Penny, A. E. Hayward Pinch, E. R. Rost, and W. B. Turnbull.

The guests were: Sir William S. Church, Bart., K.C.B., President of the Royal College of Physicians of London; Sir James Dick, K.C.B., R.N.; Surgeon-General Sir William Taylor, K.C.B., Director-General A.M.D.; Professor T. Clifford Allbutt, F.R.S.; Surgeon-General T. Walsh, A.M.D.; Mr. A. Willett, President of the Royal Medical and Chirurgical Society; Mr. Howard Marsh; Professor R. C. Leith; Dr. Dawson Williams; and Mr. Thomas Wakley, jun.

ARMY MEDICAL DEPARTMENT REPORT FOR 1901.

CONCLUDING NOTICE.[1]

IN turning over the leaves of a volume consisting altogether of 427 closely printed pages of text and tables it is impossible to do more than to select some of the more salient points for observation and to allude briefly to a few subjects which present themselves for notice. Colonel W. J. Charlton, R.A.M.C., the principal medical officer at Netley, states that the whole of the hospital drainage system was undergoing reconstruction. The flushing of the water-closets is defective, due to the action of the chlorinated water of the Hermite system. Although a useful agent for cleansing purposes its action on the metal fittings of the water-closets is destructive and may probably necessitate the provision of new fixtures. No over-crowding occurred during the year. Extra accommodation was provided in 34 Dœcker huts, each having a cubic space of 8298 cubic feet and accommodation for 10 men. The total number of invalids from abroad amounted to 6132, of whom 2851 were invalids from South Africa and 3281 from other stations abroad. Of the latter 29 died, 112 were discharged to duty, and 576 were invalided from the service. Of the South African invalids, 60 died during the year, but the full statistics of these invalids are reserved for inclusion in the campaign records.

The Principal Medical Officer, Aldershot (Colonel J. L. Notter, R.A.M.C.), remarks with reference to the establishment of systematic ophthalmic work how very important it is in these days of long ranges and modern trajectory that this should form a special branch of hospital duty, the systematic examination of the eye and the selection of lenses "when required" being more than ever necessary in the army.

At Gibraltar it is reported that considerable progress is being made with the new military hospital which is being erected there. The building is much required and must, we presume, be nearly, if not quite, completed by now (1903)

Among the sanitary changes at Bermuda it is noted that where the dry-earth system of latrines has been replaced by a water-carriage system the health of the troops has improved. As we have said in previous notices of these reports Bermuda offers, in our opinion, many facilities for carrying out an effective sewerage system and of thereby lessening, if not altogether abolishing, its liability to outbreaks of enteric fever in the future.

Passing on to the section dealing with the health of the European army serving in India we find that the average strength of these troops was much less in 1901 than it was during the preceding ten years. This was owing to the non-replacement of the troops sent to South Africa in 1899. The following table shows the admission, death, invaliding, and constantly sick ratios amongst the troops during the year 1901.

Average strength.	Ratios per 1000 of strength.				
	Admissions.	Deaths.	Invalids sent home.	Invalids finally discharged.	Constantly sick.
60,838	1104·3	13·12	39 28	8 60	66 90

The health of the troops was exceptionally good, the admission ratio was lower than that for any of the preceding 20 years, and not since 1883 have the death and constantly sick rates been less.

Enteric fever showed a decrease in 1901 of 10·8 in the admission ratio and of 2·95 in the death-rate as compared with the decennial average rates. The disease caused 26 82 per cent. of the deaths from all causes in the command in 1901 as compared with 32·65 per cent. in 1900 The satisfactory decrease in the prevalence and mortality of this fever which took place in 1899 and 1900 was maintained in 1901. The admission rate had not been so low since 1887 and the death-rate was less than it has been in any year since 1884. Whether this improvement will be maintained when the ordinary system of relief has become thoroughly re-established remains to be seen It is in the meanwhile noteworthy that although the admission rate amongst the men in their first year of service in India has remained about the same there has been a decided decrease amongst the men in their second year of service, and, indeed, all the different age periods This would indicate that some other causes besides age and acclimatisation or mere survival of the fittest must have been at work. In the case of officers we find that the admission ratio for enteric fever in 1901 was 17·8 per 1000, against 21·9 in the previous year, and as compared with an admission ratio of 12·8 per 1000 amongst the warrant officers, non-commissioned officers and men during the year under report. The percentage of mortality to attack was 28·12, as compared with 23·07 in 1900, and with 26·03 amongst the warrant officers, non-commissioned officers, and men during 1901. The cases were distributed over 20 stations.

Under the heading of surgical operations we find that the total number of these recorded among the British troops serving in India for the year was 687 and of deaths following operation 78. Of the 143 operations on the abdomen it is noted that 98 were for abscess of the liver.

It seems worth while mentioning that in the report on Egypt and Cyprus it is noted that during the year the open-air treatment of tuberculous disease was introduced at the station hospital, Cairo. The Egyptian climate and the fine situation of the citadel would naturally lend themselves to the purpose and the medical officer in charge reports highly of the favourable results that have been obtained and in many of the cases of the relatively rapid relief and improvement that have followed on the adoption of continuous open-air life and treatment.

---

[1] The previous notice was published in THE LANCET of June 6th, 1903, p. 1609.

The first paper in the appendix is Major R. H. Firth's Report on the Progress of Hygiene for the year 1901–02, and to this we would call particular attention, because it strikes us as a really useful and interesting *précis* of all that has been known and done up to date, accompanied by a running commentary from the pen of the Professor of Military Hygiene at Netley which adds considerably to its value. It would simply be tedious to enumerate all the subjects passed in review by Major Firth. The paper should be read *in extenso*. Those portions of it dealing with scarlet fever, the influence of hospital isolation, and the bacteriology of that disease, the remarks regarding the recent recrudescence of small-pox and the bacteriology and efficacy of vaccine, and more especially those portions of the report dealing with the enteric fever problem and the recent advances made in our knowledge regarding the transmission and prevention of yellow fever, will well repay perusal. The report on the work done in the surgical division of the Royal Victoria Hospital, Netley, in the year 1901–02, by the professor and assistant professor of military surgery will be referred to with interest. Considerably more than 400 operations have been performed during the year, which is a great increase over the numbers of any previous year. The increase is due almost entirely to cases of gunshot wounds from South Africa (the report is illustrated by some excellent stereoscopic skiagraphs) and to operations for the radical cure of hernia. With regard to South Africa, we may, however, very well await the anticipated appearance of an official report of the Medical and Surgical History of the War. We notice that 13 cases of abscess of the liver were operated on during the year; of these only four recovered and nine died. One of these patients was moribund on arrival at Netley; he was operated on and died on the day of arrival. Of the cases, five gave a definite history of dysentery, in four no cause could be ascribed, in two the abscess followed enteric fever, in one debility, and in one Mediterranean fever. In five of the fatal cases the relatives would not allow a post-mortem examination; details are given of the remaining four.

The report on the Medical History of the Campaign, China Field Force, 1900–01, which concludes the papers in the appendix, is mainly of interest to military medical officers.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on June 11th, the President, Sir HENRY G. HOWSE, being in the chair.

Diplomas of Fellowship were issued to 30 successful candidates.

A recommendation from the Board of Examiners in Dental Surgery was adopted. It was to the effect that candidates for the Licence in Dental Surgery should be required, when presenting themselves for examination in mechanical dentistry, to provide themselves with the following instruments, hitherto provided by the College: wax spatula (double ended), sculptors, gouge and handle, vulcanite files, gold files, pin-roughing and bending pliers, snipe-nose pliers, cutting nippers, broaches and handles, fret saw, one Melotte's moulding outfit, one Bunsen burner (laboratory), fine saws, special chasers, blowpipe for mouth (12 in.), solder tweezers, crown holder, curved shears, N.P. collar pliers, plain pin nippers, riveting hammer, and dividers (4½ in.). The following will be supplied by the hospital at which the candidates are examined—viz.: hammers for striking up plates, horn mallets, and ordinary casting materials and apparatus.

The f[illegible] appointed :—

[illegible] yle, W. G. Ridewood, T. G. St[illegible]

Anatomy (Conjoint Examining Board).—C. Addison, Arthur Keith, A. Thomson, and H. J. Waring.

Physiology (Conjoint Examining Board).—T. G. Brodie, G. A. Buckmaster, and W. H. Thompson.

Anatomy (Fellowship).—C. Addison, L. A. Dunn, A. Keith, and A. H. Young.

Physiology (Fellowship).—De Burgh Birch, L. E. Hill, E. W. Reid, and E. H. Starling.

Midwifery (Conjoint Examining Board).—G. F. Blacker, W. Duncan, A. H. N. Lewers, and J. H. Targett.

Public Health.—Part I., A. G. R. Foulerton; Part II., S. A. M. Copeman.

Mr. W. F. Haslam of Birmingham was elected a member of the Court of Examiners.

The President reported that a doctor's signboard, dated 1623, formerly the property of Mr. Manley Sims, had been purchased by the College.

The President also reported that he had purchased, on behalf of the College, a portrait by George Richmond, R.A., of the late Mr. Henry Hancock, President of the College in 1872.

A letter was read from Mr. D. B. Balding, F.R.C.S., of Royston, presenting to the College: (1) a small Prentice bleeding bowl bearing the date 1671, and (2) a hydrocele trocar (figured in vol. i., p. 420, third edition, of Benjamin Bell's Surgery, Edinburgh, 1787). The best thanks of the Council were given to Mr. Balding for his interesting gifts.

A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at its late session. The best thanks of the Council were given to Mr. Bryant for his services as the representative of the College on the General Medical Council.

The consideration of Mr. A. W. MAYO ROBSON'S motion—

> That a committee be appointed to consider the anomalies of the coroner's court in its relation to the medical profession,

was postponed.

A vote of thanks was unanimously given to Mr. Alfred Willett and Sir Frederick Treves, Bart., K.C.V.O., for their services to the College while members of the Council.

Looking Back.

FROM

THE LANCET, *SATURDAY*, JUNE 18, 1825.

LECTURES ON THE PRINCIPLES AND PRACTICE OF PHYSIC,

BY DR. ARMSTRONG.

Theatre of Anatomy, Webb Street.

LECTURE 29.[1]

If you were called to a patient affected with the simple form of scarlet fever, what would you do? The best thing at first, when the skin has become uniformly hot, is to wash the patient all over with tepid water; procure a large shallow tub, a common washing tub, and let the patient sit on a three-legged stool in the middle of it, the feet being covered by warm water; sponge the skin with warm water, then wipe it perfectly dry, and put him to bed between clean sheets. Give about two grains of calomel with a little rhubarb, and a dose of cold drawn castor oil a few hours afterwards. Let the diet be then arrowroot, and the drink cold water; pursue this plan in a cool airy apartment for three or four days, and the patient will generally be convalescent. Be careful not to expose him to cold then, as he might become dropsical. Our systematic writers have made dropsy almost a necessary consequence of scarlatina, but this is not the fact. I have seen, within the last six years, at least four hundred cases of scarlet fever, and I have only seen a *single* case in which dropsy occurred, which was owing to my directions being disregarded. The patient crammed himself with new bread, and cold or cramming are its usual causes. Dropsy, so far as I have observed subsequent to scarlet fever, arises often from inattention on the part of the patient, and occasionally from ignorance on the part of [illegible]

The treatme[illegible] fever must be regulated acc[illegible] are called to a patient in whom the fever is ardently developed, and the throat much inflamed, apply eight or ten leeches to the part; sponge the surface of the body in the way I have mentioned, or pour about two gallons of tepid water at once over the whole surface. In the next place, give a brisk aperient, as a combination of calomel and rhubarb or jalap, followed up by an infusion of senna with sulphate of magnesia. Use a gargle also composed of diluted sulphuric acid with a little syrup; keep the patient at rest in the recumbent posture, and keep him very cool, and on a very spare diet. This is the plan that I usually adopt.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE wet weather last Sunday has considerably reduced the sums which might have been collected and many of the clergy have written to us to this effect. In a large number of churches it is intended on Sunday next to make an appeal to those who were absent last Sunday to add their contributions to the amount collected on that occasion. No doubt many will gladly avail themselves of this opportunity. The Lord Mayor, in a letter to the press which we publish this week, has appealed to the clergy to place the situation before their congregations to-morrow and to invite contributions to be sent to themselves or directly to his Lordship. This we are sure—gratefully sure—the majority of the clergy will do, although the increased trouble thus entailed upon them is very serious. It is too early at present to attempt to forecast what the grand total of the Fund for this year is likely to be, but the unfavourable weather has, we fear, spoilt all chance of its reaching the much-coveted and badly-needed £100,000. The following are some of the chief amounts received at the Mansion House, or notified directly to us as having been collected, on behalf of the Metropolitan Hospital Sunday Fund up to Wednesday last:—

	£	s.	d.
St. Paul's Cathedral	5250	0	0
St. Michael's, Chester-square	1405	0	0
"In Memoriam, S. L., died May 1, 1895"	500	0	0
All Saints', Ennismore-gardens	460	0	0
Theistic Church, Swallow-street	280	0	0
Emmanuel Church, Wimbledon	203	0	0

rent Church, Enfield	35	0	0

BANQUET TO SIR JOHN WILLIAMS.

SIR JOHN WILLIAMS, Bart., K.C.V.O., M.D., F.R.C.P., having decided to retire from professional work and to reside in the county of his birth, Carmarthenshire, a large number of leading members of the profession and others who occupy notable positions in Welsh circles resolved to entertain him at a banquet and this was arranged for the evening of June 12th at the Royal Hotel, Cardiff.

At the banquet, over which the Mayor of Cardiff (Alderman Thomas, J.P.) presided, amongst those present were:—Principal Griffiths and Dr. A. F. Dixon (of the University College), Sir Alfred Thomas, M.P., Dr. Edwards (the *doyen* of Cardiff practitioners), Dr. Griffiths, Mr. Ebenezer Davies (Swansea), Principal Rhys (Oxford), Judge Gwilym Williams, Mr. J. Lynn Thomas, C.B., Mr. C. Biddle (Merthyr), Mr. Evan N. Davies, J.P. (Penygraig), Mr. Ivor H. Davies (Weston-super-Mare), Dr. M. O Davies (Cardiff), Dr. Maurice G. Evans, Dr. P. Rhys Griffiths, Dr. Pritchard, Dr. A. Garrod Thomas, Dr. T. H. Morris, Dr. C. T. Vachell, Dr. W. Williams, Dr. W. Mitchell Stevens, Dr. W. Sheen, Dr. J. J. Buist, Mr. W. F. Brook (Swansea), Mr. E. Tenison Collins, Dr. Herbert Cook, Dr. F. P. S. Cresswell, Mr. H. L. Hughes (Dowlais), Dr. J. D. Jenkins (Pentre), Dr. S. Cromwell Jones (Merthyr Tydvil), Mr. S. Lloyd Jones (London), Dr. J. Howard-Jones (Newport), Dr. Cyril Lewis, Dr. Henry Lewis, Dr. E. J. Maclean, Dr. William Martin, Mr. D. Naunton Morgan (Clydach), Mr. G. Neale, J.P. (Barry), Dr. Donald R. Paterson, Dr. R. Pritchard, Dr. J. H. Rees (Penarth), Mr. J. Robinson (Cardiff), Dr. Scholberg (University College, Cardiff), Mr. T. Stevens, Dr. William Taylor (Cardiff), Dr. W. E. Thomas (Ystrad), Mr. D. J. Thomas (medical officer of health, Merthyr Tydvil), Dr. A. Garrod Thomas (Newport), Dr. Tatham Thompson, Mr. J. Llewellyn Treharne, Dr. A. H. Trowm, Dr. E. Walford, Mr. T. J. Webster, J.P., Mr. C. J. Weichert (Penygraig), Dr. William Williams (medical officer ot health of Glamorganshire), Mr. J. H. Williams (Aberavon), and Mr. D. J. Williams (Llanelly).

Sir John Williams was received with great enthusiasm. The after-dinner proceedings were characterised by much animation and appreciative references to the character and record of the guest of the evening.

In returning thanks for the toast of "The Services" Colonel QUIRK, C.B., referred to the typhoid-infected blankets, responsibility for which, he said, folk had been trying to saddle upon the army, but now the medical equipment had become the object of attack in this connexion. The medical officers ought, it was contended by the critics, to have seen that these coverings were destroyed at the inception of the outbreak, but he was confident that the medical profession would be quite equal to vindicating its own cause and case.

The MAYOR then gave the toast of the evening, "Sir John Williams," and in doing so referred to the profound sentiment of affection which Sir John Williams, in spite of the strain of heavy professional responsibilities and a career of strenuous application, cherished for his native country. This was shown in the peerless collection of Welsh books and manuscripts which he had gathered together and which constituted a really great library. The place which he occupied in the confidence of illustrious circles was indicated by the notable fact that Sir John Williams had been decorated with the Victorian Order by His Majesty the King in person. He (the Mayor) hoped now Sir John Williams had returned again to Wales to live amongst them that these after days would be serene and unclouded and that Wales would be privileged to benefit again by the interest which Sir John Williams felt in the advancement of its progress and general welfare. There was one particular sphere in which Sir John Williams could be an incalculable service to them as Welsh people, and that was in relation to the medical school which it was sought to establish at Cardiff. They were very anxious that this should be the means of furthering developments of science and study in the Principality and he commended to the notice of Sir John Williams the fact that he might come from his Carmarthenshire home to Cardiff and stay in the Welsh metropolis for three hours and afterwards go home and be in time for dinner.

Sir ALFRED THOMAS, M.P., as representative of the Welsh

University College, also spoke to the toast and referred with enthusiasm to the perseverance, courage, and integrity which had been evidenced by Sir John Williams in the course of a striking career. Sir John Williams had come back to his countrymen in the zenith of his fame with a clean bill of health, sails all set, dropping anchor in the haven of his old home. It was not for him to suggest to Sir John Williams what he should do now. That would be both a delicate and a perilous task, and besides a superfluous one, for Sir John Williams knew very well how best to act. But he would join with the Mayor of Cardiff in expressing a deep desire that Sir John Williams should ally himself with the medical school of the University College which, he remarked amid much applause and laughter, he believed to be the "best college on earth."

The toast was received with prolonged cheering and musical honours, and Sir JOHN WILLIAMS, who appeared moved by the greeting which was accorded to him, rose to reply to the toast. To acknowledge such generous appreciation, he said, was difficult—almost as difficult an ordeal as that which one experienced when lecturing for the first time to that extremely wideawake class of critics, the medical students. He could only thank his friends very warmly and sincerely for their goodwill. Some while ago he had been asked by one of the newspapers which enjoyed a large circulation to give its columns some of his reminiscences. He felt that these were such as could not appear in such circumstances. And so in expressing his gratification at the sentiments which were manifested towards him he must now confine himself to his very sincere acknowledgments. But he was glad to see amongst them so many old friends, and especially glad to see Mr. Ebenezer Davies of Swansea who had given him his start in the medical profession and bestowed upon him much valued advice.

Sir John Williams resumed his seat amid renewed cheers.

[illegible] Dr. T. [illegible] of he [illegible] to the "land of his fathers"; and it wa[illegible] dentally that Swansea intended to give to [illegible] very [illegible] rked [illegible] en ha[illegible] All Welshmen were proud of a man who from his very student days right on to these meridian hours of life had ever been instinct with the inspiration of hard work and great abilities greatly applied. It was something for them to be glad that when those who professed chill scepticism as [illegible] of Welsh people put the [illegible] "Where are your Welsh-[illegible]e to point to their guest of the evening as one of those who brought to the records of Wales a lifetime of service and honour.

Professor RHYS in replying to the toast of "The University of Wales" pointed out that it would be of incalculable advantage to Wales and those connected with the promotion of its educational and social interests if on questions which demanded an expert knowledge of medicine and medical matters they were able to have the counsel and assistance of so great an authority as Sir John Williams.

Sir JOHN WILLIAMS afterwards proposed "The South Wales and Monmouthshire University College" and delivered an address in which he dealt with the Celtic character. He minutely compared Wales with Scotland and predicted, in spite of the drawbacks which handicapped Welsh students, better things and more substantial results in days to come. The dawn was breaking and this was evidenced by the success of their medical school at Cardiff. Half a century had wrought an immense change in the condition of the Welsh people. He noted with satisfaction that the South Wales College differed from the other Welsh colleges in having a faculty of medicine where the future medical men of Wales would be trained. He hoped that before long the University of Wales would have powers to [illegible] and explained that finan-[illegible]uthshire College could not go on much longer as now, for if help was not forthcoming the fees would have to be raised. As for the medical school, he grieved that they were about to lose their valued colleague, Professor Dixon.

Professor DIXON also responded and said that considerable distinction had characterised the career of some of the students of the medical school at the Cardiff College.

Vocal and instrumental selections were given during the evening and the whole proceedings were very pleasant and successful, this result being due in a large degree to the admirable arrangements of Mr. Austin Jenkins (the registrar of the University College) and Mr. Lynn Thomas.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9343 births and 4022 deaths were registered during the week ending June 13th. The annual rate of mortality in these towns, which had been 15·5, 14·9, and 14·3 per 1000 in the three preceding weeks, further declined to 13·9 per 1000 last week. In London the death-rate was 12·4 per 1000, while it averaged 14·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 4·7 in Hornsey, 5·3 in Smethwick, 5·7 in Willesden, 6·4 in Walthamstow, 8·5 in Croydon and in York, 9·0 in Tottenham, and 9·1 in Handsworth; the highest rates were 18·8 in Oldham, 19·3 in Liverpool, 19·4 in Burnley, 19·6 in West Bromwich and in Preston, 21·5 in Coventry, 22·5 in Middlesbrough, and 25·1 in Great Yarmouth. The 4022 deaths in these towns last week included 404 which were referred to the principal infectious diseases, against 461, 434, and 397 in the three preceding weeks; of these 404 deaths 124 resulted from measles, 77 from diarrhœa, 76 from whooping-cough, 56 from diphtheria, 39 from scarlet fever, 19 from "fever," and 13 from small-pox. No death from any of these diseases was registered last week in Brighton, [illegible] ow, Wolverhampton, Coventry, Wigan, [illegible] esbrough; from diphtheria in Great [illegible] try; from whooping-cough in Oldham [illegible] from "fever" in West Bromwich [illegible]; and from diarrhœa in Great Yarmouth and Hanley. The mortality from scarlet fever showed no marked excess in any of the large towns. Of the 13 fatal cases of small-pox registered during the week three belonged to Liverpool and one each to Leicester, Derby, Bootle, Bolton, Manchester, Oldham, Rochdale, Halifax, Bradford, and Sunderland. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals which had been 64, 60, and 72 at the end of the three preceding weeks, had declined again to 64 at the end of last week; nine new cases were admitted during the week, against 19, 10, and 24 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday, June 13th, was 1710, against numbers increasing from 1662 to 1785 on the eight preceding Saturdays; 145 new cases were admitted during the week [illegible] ceding weeks. [illegible] tory organs in L[illegible] in the three preceding weeks, further declined last week to 141 and were 59 below the number in the corresponding period of last year. The causes of 45, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Birmingham, Nottingham, Newcastle-on-Tyne, and in 50 other smaller towns; the largest proportions of uncertified deaths were registered in Grimsby, Liverpool, Manchester, Sheffield, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·2, 18·4, and 18·2 per 1000 in the three preceding weeks, further declined to 17·5 per 1000 during the week ending June 13th, but was 3·6 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·7 in Dundee and 13·8 in Paisley to 18·8 in Glasgow and 23·3 in

Greenock. The 574 deaths in these towns included 20 which were referred to whooping-cough, 20 to diarrhœa, three to measles, three to scarlet fever, two to "fever," and one to diphtheria, but not one to small-pox. In all, 49 deaths resulted from these principal infectious diseases last week, against 51, 70, and 65 in the three preceding weeks. These 49 deaths were equal to an annual rate of 1·5 per 1000, which was slightly above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 22, 28, and 25 in the three preceding weeks, further declined last week to 20, of which 10 occurred in Glasgow, four in Greenock, and three in Edinburgh. The deaths from diarrhœa, which had been 18 in each of the two preceding weeks, increased to 20 last week and included 11 in Glasgow, three in Edinburgh, and three in Aberdeen. The fatal cases of measles, which had been six, seven, and nine in the three preceding weeks, declined again last week to three. The deaths from scarlet fever, which had been six and seven in the two preceding weeks, decreased again to three last week; while the two fatal cases of "fever" corresponded with the number in the preceding week. The deaths referred to diseases of the respiratory organs in these towns, which had been 114 and 111 in the two preceding weeks, further declined last week to 75, and were 54 below the number in the corresponding period of last year. The causes of 23, or more than 4 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·4, 22·2, and 22·2 per 1000 in the three preceding weeks, declined again to 22·4 per 1000 during the week ending June 13th. During the past four weeks the death-rate has averaged 22·4 per 1000, the rates during the same period being 13·7 in London and 17·3 in Edinburgh. The 163 deaths of persons belonging to Dublin registered during the week under notice showed a decline of two from the number in the preceding week and included nine which were referred to the principal infectious diseases, against 11, seven, and ten in the three preceding weeks; of these five resulted from whooping-cough, two from "fever," one from small-pox, and one from scarlet fever, but not one from measles, from diphtheria, or from diarrhœa. These 19 deaths were equal to an annual rate of 1·2 per 1000, the death-rates last week from the principal infectious diseases being 1·2 in London and 1·3 in Edinburgh. The fatal cases of measles, which had been one, two, and one in the three preceding weeks, increased again last week to five. The deaths from "fever," which had been two, one, and three in the three preceding weeks, declined again to two last week. One fatal case of small-pox was registered last week, against four, none, and three in the three preceding weeks. The 163 deaths in Dublin last week included 29 of children under one year of age and 38 of persons aged upwards of 60 years; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a marked decline. Five deaths from violence and five inquest cases were recorded; and 57, or more than a third, of the deaths occurred in public institutions. The causes of ten, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon A. Kidd to the *Hood.* Staff Surgeons: R. Hill to the *Victory;* H. B. Marriott to the *Tribune;* E. St. M. Nepean to the *Æolus;* W. G. Stott to the *Melampus;* and R. Miller to the *Spartan.* Surgeons: W. N. L. Cherry to the *Hood;* S. H. Woods to the *Pembroke,* additional for disposal. Civil Practitioner R. Magill to be Surgeon and Agent at Newcastle and Dundrum.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Thomas A. Dixon retires on retired pay. Dated June 13th, 1903.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant-Colonel G. R. T. Phillips having resigned his appointment in the Imperial Yeomanry ceases to be an officer in the Army Medical Reserve of Officers. Surgeon-Lieutenant E. Downes having resigned his appointment in the Volunteers ceases to be an officer in the Army Medical Reserve of Officers.

IMPERIAL YEOMANRY.

The undermentioned gentlemen to be Surgeon Lieutenants:—John Leach (dated June 10th, 1903) and John Robert Kennedy (dated June 10th, 1903).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Hampshire: John Henry Frederick Way, late Captain, to be Surgeon-Lieutenant. Dated June 13th, 1903.

Submarine Miners: The Tay: John Yule Mackay to be Surgeon-Lieutenant. Dated June 13th, 1903.

Rifle: 2nd Volunteer Battalion the Royal Warwickshire Regiment: Surgeon-Lieutenant J. Orton to be Surgeon-Captain. Dated June 13th, 1903. 4th Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Lieutenant A. F. Wilson-Gunn to be Surgeon-Captain. Dated, June 13th, 1903. 22nd Middlesex: Surgeon-Captain W. J. Harnett resigns his commission and is granted the honorary rank of Surgeon-Major, with permission to wear the uniform of the corps on retirement. Dated June 13th, 1903. 1st Cadet Battalion the King's Royal Rifle Corps: Surgeon-Lieutenant R. Roche to be Surgeon-Captain. Dated June 13th, 1903. 1st (Hallamshire) Volunteer Battalion the York and Lancaster Regiment: Surgeon-Major J. W. Martin to be Surgeon-Lieutenant-Colonel. Dated June 13th, 1903. 2nd Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant H. G. Cowie resigns his commission. Dated June 13th, 1903.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Manchester Companies: Lieutenant W. L. Bentley to be Captain. Dated June 13th, 1903.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

Welsh: Lieutenant A. W. Sheen to be Captain. Dated June 13th, 1903.

THE MEDICAL CORPS OF THE UNITED STATES NAVY.

The Fifty-seventh Congress in its last session, states the *Maryland Medical Journal,* provided for an increase of 150 members in the Medical Corps of the Navy, 25 of whom are to be appointed each calendar year for six years. By the enactment of this law there is afforded to the young physicians of America an opportunity to take service in the navy of the United States and an assurance of the continuance of this opportunity for the next six years. The future prospects of the medical officer of the navy, both for promotion and professional opportunity, are very bright, says our American contemporary, and the plan of enlargement of the naval establishment already adopted and authorised, as well as that in contemplation, gives assurance that this outlook will grow even more promising. The Medical Corps of the United States Navy consists at the present time of the following numbers and grades. One surgeon-general with the rank of admiral (equivalent to brigadier-general in the army); 15 medical directors with the rank of captain (equivalent to colonel in the army); 15 medical inspectors with the rank of commander (equivalent to lieutenant-colonel in the army); 85 surgeons with the rank of lieutenant-commander (equivalent to major in the army); 23 passed assistant surgeons with the rank of lieutenant (equivalent to captain in the army); 56 assistant surgeons with the rank of lieutenant, junior grade (equivalent to first lieutenant in the army). There are 27 vacancies in the grade of assistant surgeon for the year 1903.

ARMY CANTEENS.

As our readers are aware, a controversy has been going on for some time on the subject of army canteens which, seeing that it affects the social comfort, health, and general well-being of the soldier, is not altogether without medical interest. By a recent order the War Office has modified its previous announcement that army canteens were to be conducted on the regimental system. It has now been wisely left to the army to manage its own canteens in its own way. Power is given to those in direct command of troops to follow the particular system which is preferred by the corps unit and is thought likely to prove most advantageous to the soldier. So many objections have been urged by officers of experience against the working of the regimental system on its old lines and, on the other hand, there are so many reasons in favour of the tenant system, that the War Office has been driven to adopt the wise course of leaving the matter in the hands of the local military authorities.

PARTURIUNT MONTES.

It is a very curious circumstance which cannot have escaped observation that whenever there is any unusual talk of military reform the more immediate, and sometimes the only apparent, result is some alteration or other in the officer's or soldier's dress. The ugly flat pancake cap to be seen on the heads of Guardsmen is closely followed by a question as to whether a white collar is allowable or not in uniform, and if so, the exact amount of it permitted to be visible. It can scarcely be said that these changes were necessary or desirable in a hygienic or artistic point of view.

ROYAL NAVY MEDICAL SERVICE.

We are extremely glad to notice that Staff-Surgeons E. B. Townsend and P. B. Handyside have been recently promoted
icuous professional merit.
It is a
und principle on the part
of the
congratulate the officers
in question.

Correspondence.

"Audi alteram partem."

METROPOLITAN HOSPITAL SUNDAY FUND.

To the Editors of THE LANCET.

SIRS,—The deplorable weather on "Hospital Sunday" prevented so many people from going to their places of worship that the collections on that day have been half ruined. It will be a lasting pity if when the needs of the hospitals are so especially pressing and when our generous benefactor, Mr. George Herring, is again offering to add a quarter to all the church and chapel offertories sent in, the result of the Fund this year should be so lamentably below the average.

In these circumstances I venture to appeal to the clergymen and ministers to state these facts to their congregations next Sunday and to invite those who were absent on Hospital Sunday to remit their customary contributions either to them or to me. It would, I suppose, be too much to ask that the offertory at one of the services at least should be dedicated to the Hospital Sunday Fund?

I am, Sirs, yours faithfully,
MARCUS SAMUEL, Lord Mayor.
The Mansion House, London, E.C., June 17th, 1903.

ASSOCIATION OF MIDLAND RAILWAY SURGEONS.

To the Editors of THE LANCET.

SIRS,—The first annual general meeting of the above association will be held at the Wyvern Hotel, Leicester, on Thursday, June 25th, at 3.30 P.M. As important business is to be transacted it is desirable that all the surgeons to the Midland Railway Friendly Society should make an effort to attend, and, Sirs, if you will kindly give prominence to this announcement in your valuable journal it will greatly assist by enabling those Midland railway surgeons whose names are still unknown to the association to attend the meeting or to communicate with me so that if they wish their names may be added to the existing list of members.

I am, Sirs, yours faithfully,
A. E. PAYNE,
Honorary Secretary, *pro tem.*
2, Melbourne-street, Leicester, June 16th, 1903.

A NEW METHOD OF DETECTING PLAGUE BACILLI IN BLOOD.

To the Editors of THE LANCET.

SIRS,—The difficulty in detecting plague bacilli in the blood is so well known that we venture to bring to your notice a method which has hitherto given us very good results in all cases, both early and late. It will be found very useful to those in charge of general hospitals where it is difficult to keep out plague cases and where one is anxious to come to a diagnosis as early as possible. The blood film should be taken by Ross's method, making the film a little larger and thinner than for malaria; decolourise and stain, when plague bacilli will invariably be found. All our last cases have been diagnosed in this way and the diagnosis confirmed at the infectious hospital.

We are, Sirs, yours faithfully,
J. BELL,
Superintendent;
E. A. R. LAING,
Assistant Superintendent.
Government Civil Hospital, Hong-Kong, May 14th, 1903.

BLOOD PRESSURE.

To the Editors of THE LANCET.

SIRS,—May I ask Dr. Oliver why, in his address entitled "A Few Jottings in Physiological Medicine," he estimates blood pressure in terms of *cubic* millimetres of mercury? I thought at first that the word "cubic" must be a misprint, but as it occurs throughout the address it is apparently intentional. Pressure is measured by the height of a column of mercury (or other fluid) and not by its volume. With regard to the rise of blood pressure at high altitudes, will not this be explained by a diminution of the partial pressure of the oxygen? The pulse-rate has been found, in balloon ascents, to increase with the height up to 24,000 feet.

I am, Sirs, yours faithfully,
CHARLES POWELL WHITE.
St. Thomas's Hospital, S.E., June 16th, 1903.

THE UNRESTRICTED OUTPUT OF INFLAMMABLE COMBS.

To the Editors of THE LANCET.

SIRS,—You have, I think, several times called attention to the danger of using dressing combs prepared from xylonite or other analogues of gun-cotton. The risk appeared to me to be very trifling, but that view has been modified by the case of a young girl who was lately brought to me suffering from cellulitis of the scalp. It seems that she was in the habit of wearing a comb in her hair and one Sunday, whilst preparing her father's dinner, she held down her head in front of the fire. Suddenly the comb became ignited and burned up with a flash, setting fire to her hair. She fell on the ground in a faint, but luckily her brother had the presence of mind to wrap a coat around her head and to extinguish the flames, leaving her, however, in a state of collapse and with other effects of the accident from which she did not recover for weeks.

I understand that the original patent for making combs from xylonite has expired and that now the markets are flooded with imitations which are much more liable to ignition than the original. Surely, then, some restriction ought to be placed on their sale or at least the purchaser ought to have fair warning of the risk.

I am, Sirs, yours faithfully,
J. C. MCWALTER, M.D. Brux., D.P.H.
Dublin, June 13th, 1903.

ASEPTIC AND ANTISEPTIC SURGERY.

To the Editors of THE LANCET.

SIRS,—I have read with great interest Mr. Henderson's remarks in THE LANCET of June 13th, p. 1697, and entirely agree with him. By strictly adhering to aseptic and antiseptic methods it is quite possible for a general practitioner to undertake some of the major operations of surgery with most gratifying results. During the last three years I have performed three laparotomies for ectopic pregnancy, suppurating ovarian cyst, and a cyst of the right broad ligament,
[illegible] in the inguinal canal. In every
ion, although these operations
ent's home. I also amputated
and did a good many minor
it of strict asepsis and anti-
sutures, and dressings. I
invariably see that the room is thoroughly disinfected and stripped of carpets, mats, dirty curtains, &c., prior to the operation. With these precautions my experience is that

returning from Egypt, owing to typhoid fever contracted in the lazaretto at Frioul. M. Teissier, at the meeting of the Academy of Medicine held on June 2nd, complained of the whole French sanitary service in which, he said, nothing is done to guard against the entry of infectious diseases at French ports, although every custom which can annoy passengers is religiously observed. The disinfection of ship, cargo, and of passengers' baggage is absolutely illusory. Bales of merchandise which very probably shelter plague-stricken rats and the mail-bags are disembarked without any disinfection. The baggage of passengers is not opened but is simply sprinkled with a weak solution of sublimate. In 1902 the ship *Portugal* arrived at Marseilles from Alexandria where plague was prevalent. Hundreds of bales of cotton full of rat-holes were disembarked and without more ado were given free pratique. As for the disinfection of personal effects each passenger was compelled to give up nothing but a pair of socks, a handkerchief, and a shirt. The excuse given was that the disinfecting stove was too small to take all the dirty linen of the passengers. The rest of the baggage was allowed to enter Marseilles without any other formality. M. Teissier compared this method with the English system which, according to him, works tactfully and protects the ports while conserving the rights of individuals and does not interfere unduly with trade. The French method comes to an end with a vexatious imprisonment in a barrack, as badly managed as possible. "Suspects" stay there for a term the duration of which is arbitrarily fixed by the director of the Sanitary Department. When this term is ended anyone can go where he likes and thus if later plague should declare itself such person becomes a focus of infection in an inland town without the sanitary authorities having had any warning. M. Teissier argued that preventive injections of anti-plague serum are a certain safeguard against the development of the disease in persons coming from an infected region if there is no sign of plague on them at the port of entry and it would be easy to make such injections compulsory. Finally, M. Teissier proposed that a consultative committee of control should be nominated to sit conjointly with the authorities of the sanitary service and to this committee should be assigned for judgment all cases of litigation and the duration of the quarantine should also be fixed by it. He demanded also the suppression of the discretionary power of the director of the Sanitary Department, for this official, as things now stand, can refuse entry to France of Frenchmen sailing under a foreign flag. As a consequence, during the rest of their voyage, which may last ten days, to Plymouth or London these unfortunate people, who may be coming home ill, though not infectious, are quite likely to die on the way and to be then buried at sea. In a word, M. Teissier considers that the whole French sanitary service should be reorganised, due consideration being given to preventive injections of serum, and he recommended the introduction of the English system of a sanitary passport which provided safety and was not so vexatious as imprisonment. The Academy will shortly proceed to the discussion of this important matter.

June 16th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Plague in Berlin.

As already mentioned in THE LANCET of June 13th, p. 1684, a young medical man has just lost his life in Berlin in very sad circumstances and another name has been added to the long list of medical martyrs to science. The deceased was Dr. Milan Sachs of Agram in Croatia, who had been sent by the Austrian Government to Berlin for the purpose of studying infectious diseases in Professor Koch's Institute. He fell ill on June 2nd and in the evening of June 4th he became so much worse that he was admitted into the municipal hospital of Charlottenburg, a suburb of Berlin where he lived. The symptoms appeared to point to pneumonia, but when it became known that the patient had worked in Professor Koch's laboratory, and especially in the plague department, the sputum was carefully examined, with the result that plague bacilli were found and Dr. Sachs was thereupon immediately removed with the utmost precautions to the department for infectious diseases which belongs to Professor Koch's Institute and is in connexion with the Charité Hospital. Here he received injections of Roux-Yersin serum, but notwithstanding all that could be done he unfortunately succumbed on the evening of the 5th. For the purpose of discussing the measures which it might be necessary to take in view of the possibility that the disease might spread a meeting was at once held in the Charité Hospital, under the presidency of the chief of the Berlin police, those present including officials of the Imperial Health Office, the chief medical officer of the Berlin police, the medical member of the Berlin town council, and the medical staff of the Charité Hospital and the Charlottenburg Hospital. The meeting agreed that the fact of a case of plague having occurred in the city should be communicated to the newspapers as the best means of preventing the alarm which was likely to be created by the publication of vague and inaccurate statements. Strict isolation of all persons who had been in communication with Dr. Sachs during his illness was also ordered, and for this purpose some of the wards of the department for infectious diseases were cleared of the patients already in them and were reserved exclusively for the reception of those who had been exposed to the danger of infection with plague. Not only the family with whom Dr. Sachs had lived in Charlottenburg, but also several hospital nurses, attendants, and porters, and three medical men were isolated; no communication with them was allowed and policemen were stationed at the entrance to prevent the orders to that effect being evaded. All the furniture and articles of general use in the residence which Dr. Sachs had occupied were destroyed by fire, full value being paid to the owner by the Treasury in accordance with the provisions of the Infectious Diseases Act; the place was then completely emptied and thoroughly disinfected. Meetings of the authorities, both police and sanitary, took place nearly every day under the presidency of the Minister of Public Instruction, acting as chief of the Government medical department. It has been reported that the Government intended to prohibit the carrying on of investigations relative to plague and other virulent diseases. This is erroneous, as it is recognised that such researches are indispensable, but it is probable that experimental work will be more strictly controlled in future and that the admission of foreigners to this particular laboratory will be rendered more difficult. All those who have been placed in isolation received injections of Roux-Yersin serum. Their health has hitherto been quite satisfactory with the exception that one of the male attendants who had nursed Dr. Sachs at the Charlottenburg Hospital felt ill after admission and his temperature rose slightly, so that he was suspected of having caught the disease, but as he completely recovered after 24 hours his symptoms were attributed to the injections, especially as microscopical examination of his blood showed nothing abnormal. Subsequently, however, his sputum was tinged with blood and was found to contain virulent plague bacilli, the injections of Roux-Yersin serum were therefore continued and the patient's state is now said to be satisfactory. The public do not exhibit any alarm on the subject, being evidently convinced that all necessary precautions are being taken.

Physiological Action of the Becquerel Rays.

Dr. Loudon of St. Petersburg has published in the *Berline* *Klinische Wochenschrift* some interesting observations relativ to the action of the Becquerel rays on the nervous syste and on the eye. He found that when a box containing bromide of radium was placed in a cage in which mice wer kept the animals became paralysed and comatose and die in five days. He also found that persons who are eithe totally blind, or have only the feeblest possible perception o light, are peculiarly sensitive to the Becquerel rays and ar able to form visual conceptions of the contour of objects th shadows of which are shown on a screen by means of th rays.

June 15th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Quarantine Laws of the United States.

VESSELS arriving under the following conditions shall b placed in quarantine: (*a*) with quarantinable disease on boar or having had such disease on board during the voyage (*b*) any vessel which the quarantine officer considers infected (*c*) if arriving at a port south of the southern boundary o Maryland in the season of close quarantine, May 1st t

Nov. 1st, directly or *viâ* a northern port, from a tropical American port, unless the said port is known to be free from yellow fever; (*d*) in the case of vessels arriving at a northern port without sickness on board from ports where yellow fever prevails the *personnel* shall be detained under observation at quarantine to complete five days from the port of departure; and (*e*) towboats and other vessels having had communication with vessels subject to quarantine shall themselves be quarantined if they have been exposed to infection. Vessels arriving under the following conditions need not be subject to quarantine: (*a*) vessels from yellow fever ports bound for ports in the United States north of the southern boundary of Maryland with good sanitary condition and history, having had no sickness on board at ports of departure, *en route* or on arrival, provided they have been five days from the last infected or suspected port; and (*b*) vessels engaged in the fruit trade may be admitted to entry without detention provided that they have complied in all respects with the special rules and regulations made by the Secretary of the Treasury with regard to vessels engaged in the said trade.

To restrict Hospitals for Consumptives.

Governor Odell has signed the Goodsell-Bedell Bill prohibiting the establishment of any hospital or camp for consumptives in any town in New York State without the formal consent of the supervisors of the county and town board of the town.

Death of Dr. T. G. Morton.

Dr. Thomas G. Morton, the well-known surgeon of Philadelphia, died at Cape May, N.J., on May 20th after a short illness. Dr. Morton was born in Philadelphia on August 8th, 1835, and was the son of Samuel George Morton, himself a distinguished medical practitioner. He graduated in medicine from the University of Pennsylvania in 1856, after which he began practice as a surgeon in his own city. At the beginning of the American civil war he became actively identified with the establishing of military hospitals. He was surgeon at Satterlee Hospital and consulting surgeon to the United States Hospital at Chesnut Hill, Pennsylvania. He was the founder of the Philadelphia Orthopædic Hospital and in 1876 was appointed a commissioner to erect a State insane asylum for the southern district of Pennsylvania. He devised many mechanical improvements in hospitals, he wrote many papers on surgical matters, and published works on the transfusion of blood and its practical application. The late Dr. Morton was a member of several foreign medical and scientific bodies.

An Automobile Bill in New York State.

Governor Odell has signed the Doughty-Bailey Automobile Bill. The principal features of the new law are as follows. Speed is restricted to four miles an hour when crossing a dam or causeway less than 20 feet in width. Speed is restricted to eight miles an hour within a radius of half a mile from a post-office or a greater radius if the local authorities so elect, when passing in either direction a person driving a horse or domestic animal or passing a pedestrian in the roadway, when crossing an intersecting main highway, and in the closely built-up portions of cities. Speed is restricted to ten miles an hour when passing a public school during school hours or a church during the hours of service. Speed is restricted to ten miles an hour in the suburbs of cities where the houses are more than 100 feet apart. Speed is restricted to 20 miles an hour in the open country where post-offices, school-houses, churches, causeways, cross roads, drivers or pedestrians do not conflict. A motor must be stopped on request of a rider or driver.

June 8th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Consumption in Victoria.

COMPARATIVELY little has been done in Victoria for the treatment of early cases of consumption in sanatoriums. One institution of the kind has been established for many years at Echuca and more recently a branch of this establishment was started at Macedon. Consumptive patients, generally in advanced stages of the disease, are also received at the Austin Hospital for Incurables. The Board of Health is considering the whole question of the treatment of tuberculosis and Dr. Gresswell has just visited the sanatorium at Echuca. He considers that the area of ground is too small and that the site is not suitable because of its being shelterless and cramped and of there not being sufficient area for recreation purposes. Some of the country hospitals have offered to receive consumptive patients referred to them by the Board of Health. The Amherst Hospital will accommodate eight and the Kilmore Hospital six patients.

The Lunacy System of Victoria.

Recent criticisms of the lunacy system are commented upon in a report which the Chief Secretary has received from Dr. Jamieson and Dr. Joske, who are two of the official visitors to the metropolitan asylums. They state that their aim has been "to present an account of the institutions as they are, not passing over their defects and yet trying to be fair." They say that most, if not all, of the genuine defects recently pointed out have been made the subject of remark, and many of them repeatedly, in the official reports. It is admitted that the main building at Kew is badly planned, the construction being so defective and the means of escape so deficient and badly placed that an outbreak of fire might lead to a dreadful catastrophe. As the result of continuous overcrowding rooms which are little better than wide corridors are used not only as sitting- and recreation-rooms but also have to serve as dining-rooms. Another result of overcrowding is that some of the wards are habitually too full and they are insufficient to allow of proper classification and separation of patients. Something might be done in the way of improvement by bringing into use spaces which are little or not at all occupied. Recommendations are made that at each asylum there should be a small detached building for the prompt isolation of infectious cases; that it might be advisable to leave all cell doors unlocked at night, as could easily be done with a sufficient increase in the number of night attendants, and that there should also be a system of electric tell-tale clocks. The visitors consider that something should be done at the earliest possible date to provide a suitable receiving house. Separate provision should be made without delay for patients whose friends are willing to pay for the accommodation. "There is no doubt," they say, "that there are now places clandestinely used as private lunatic asylums. In our opinion it would be better to supply good accommodation under State supervision than to license private establishments even under Government inspection." Another recommendation is that the superintendent of each asylum should be held responsible for all that takes place in his asylum. He should be under the direction of a board of management which should have complete control of the whole department. Such a board might consist of the Minister in charge of the department, the inspector, and a capable business man. They should have the services of a special architect not connected with the public works department. The visitors say that "the approaching retirement of the present inspector gives the department an opportunity of obtaining from without the State a new head who could regard the whole question of management from a fresh point of view." The final recommendation is that one of the metropolitan asylums should be converted into a strictly curative hospital. This would mean a great reduction in the number of inmates and of necessity the erection of other buildings elsewhere. It would be desirable, the report states, to bring from some place outside the State a new superintendent for this reorganised institution.

Protection of Illegitimate Children.

Dr. Mackellar of Sydney gave an interesting lecture on April 20th on the Protection of Neglected and Illegitimate Children in New South Wales. He gave a *résumé* of previous [illegible] and explained the provisions of the [illegible] ive Council last session by him- [illegible] Careful perusal of the official statistics showed that during the last ten years 25,034 illegitimate births had taken place in that State. The very uniformity of the figures for that period indicated that in the absence of remedial measures it was fairly certain that this tale of shame and misery would be repeated during the next similar period. What was the cause? Dr. Mackellar had no hesitation in affirming his belief that certainly one of the principal causes lay in the absence of a comprehensive and drastic law which should fix upon the father of an illegitimate child the whole responsibility for his action. The illegitimate birth-rate of Sydney was 10 per cent. of the whole birth rate and of the country districts it was something more than 5 per cent., the rate altogether for the colony being rather more than 7 per cent., which was a much larger percentage than existed in any of the adjoining States and a much larger percentage than that of the United Kingdom. Moreover, in New South Wales the birth-rate as a whole had decreased 33 per cent. since 1864, while the illegitimate birth-rate had nearly doubled in that period. On the other hand, the illegitimate death-rate was just 241 per cent. higher than the legitimate—a circumstance which told its own tale. The fact that in New Zealand the illegitimate rate was only 4·42 per cent. and in South Australia only 3·76 per cent.—about half that of New South Wales—was significant, inasmuch as those were the only two Australasian communities in which there were really effective affiliation laws. It was also necessary legally to prevent the employment of children in street-trading—a species of employment which Dr. Mackellar quoted the authority of the Comptroller-General of Prisons for saying was as pernicious in its effects on the moral and physical well-being of the children following it as the factory system at its worst, at least one-half of the criminality in the State being traceable in the first instance to truancy and street-trading. Added to that was the testimony of the superintendent of the Carpenterian Reformatory at Brush Farm that 80 per cent. of the children who were committed by magistrates to that institution were sent there because of crimes having their origin in the same manner.

May 8th.

Obituary.

JOHN BIRKBECK NEVINS, M.D. LOND., M.R.C.S. ENG.

THE recent death of Dr. J. B. Nevins of Liverpool has removed one of the most prominent medical personages in that city. At the age of 84 years he had outlived nearly all the colleagues of his earlier days. As an old pupil of his I can bear testimony to his influence and powers as a teacher, especially in the subjects of the early portion of the medical curriculum. As medical tutor at Guy's Hospital he had acquired the art of teaching practically and with accuracy. I believe Sir Samuel Wilks was one of his pupils there. His knowledge of medical botany and the materia medica was the best of its time, and he taught these subjects as they are seldom taught in these days. He was ever active and studious and his reading and occupations went far outside the field of medicine. His line of practice was general but he was specially interested in ophthalmic work. Had he followed medicine only he would have certainly become more widely known than he was. He probably dissipated his energies too much. His attitude and efforts towards the Contagious Diseases Acts brought him into conflict with the main body of the profession in later life and must have cost him much pain and obloquy. But this was a matter of conscience with him, and being a deeply religious man he felt keenly the nature of the provisions relating to the working of that measure. His warmest friends had to agree to differ from him and regretted that he spent so much labour in opposing the views of others who could not see eye to eye with him. To the last, when retired from active practice, his mind was engaged with literary work and all matters of scientific or antiquarian interest enlisted his attention. He was a sincere and kind friend, simple and unassuming, content to do his duty, and guided by a fervent Christian faith. Those who best knew him will longest cherish kindly memories of him.

D. D.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced :—Dr. Selikh Yanovich-Chainski, *privat-docent* of surgery in the Military Medical Academy of St. Petersburg.—Dr. Fernando Poló y Grijalbo, professor of midwifery and gynæcology in Saragossa.—Dr. Joseph de Smeth, formerly professor of psychiatry and of general pathology in the University of Brussels.—Dr. David Haussmann, a Berlin practitioner whose name is well known as a writer on various medical subjects mainly connected with the practice of midwifery.—Dr A. Dubler, formerly extraordinary professor of pathological histology in Basle, aged 46 years.—Dr. M. Huizinga, formerly professor of physiology in Groningen, where he succeeded Professor van Deen. His published works are mostly of a chemical nature.—Dr. Franz Saxer, prosector in the Leipsic Anatomical Institute, from an abscess in the brain due to a dissecting wound.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The followin medical degrees were conferred on June 11th :—

M.D.—G. C. Garratt, Trinity.
M B.—H. Robinson, L. E. Wigram, and H. D. Ledward, Trinit J. A. Wood, St. John's; W. J. Susmann, Caius; F. H Park Pembroke; and W. W. Jeudwine, Selwyn Hostel
B.C.—H. Robinson, L. E Wigram, and G. W. Micklethwait, Trinit G. B. Norman, St. John's; and R. S. Drew, Pembroke.

The Professorship of Surgery, which has been suspend for the last five years, is declared vacant. The electi will take place during the Long Vacation. The electo are the Vice-Chancellor, Dr. L. Humphry, *Professor* Macalister, Sir M. Foster, Lord Lister, Dr. D. MacAlist Professor J. Chiene, C B., Professor T. Clifford Allbutt, a Mr. T. Holmes.—Dr. D. MacAlister, assessor to the Regi professor, has been appointed additional examiner Part I. of the third M.B. examination in pharmacology a general pathology.—Mr. J. O. Simpson, M.D. Edin., h been approved for the research degree of B.A. in virtue his dissertation, "On the Organisation of a Thrombus"

FOREIGN UNIVERSITY INTELLIGENCE.—*Basl* Dr. Albert Gassmann of Berne has been recognised as *priva* *docent* of Dermatology.—*Bonn:* Dr. Rudolf Rosemann Greifswald has been recognised as *privat-docent* of Phys logy.—*Budapest:* Dr. F. Reusz has been recognised *privat-docent* of Neurology.—*Clausenburg:* Dr. Leo Davi Professor of Descriptive Anatomy, has been ennobled recognition of his services to education.—*Kazan.* I Constantin Archangelski has been appointed to the ch of Pharmacology in succession to Dr. Dogiel. Dr. Savchen has been appointed professor of General Pathology *Leyden:* Dr. P. T. van der Hoeven of Amsterdam has be appointed to the chair of Midwifery and Gynæcology succession to Dr. Veit.—*Lyons:* Dr. Doyon has be promoted to be *professeur adjoint.*—*Marseilles:* Dr Alez has been appointed Professor of Anatomy.—*Moscow* K. A. Buinêvich has been recognised as *privat-docent* Medical Diagnosis.—*Naples:* Dr. Francesco Lastaria been recognised as *privat-docent* of Operative Medicine *New York Polyclinic:* Dr. J. A. Bodine has been pointed Professor of Surgery and Dr. Charles Kerley Professor of Pediatry.—*Odessa:* Dr. Khlopin Iurieff has been appointed to the chair of Hygiene *Rome:* Dr. Francesco Valagussa has been recognised *privat-docent* of Pediatry.—*Rostock:* Dr. Johannes Müll assistant in the Physiological Institute, has been recogni as *privat-docent* of Physiology.—*Tomsk:* Dr. Timofeiev Extraordinary Professor of General Pathology, has been moted to the Ordinary Professorship.—*Toulouse:* Dr. B has been appointed to the chair of Children's Diseases *Vienna:* Dr. W. Mitlacher has been recognised as *pri* *docent* in Pharmacology and Dr. Karl Strernberg as *pri* *docent* of Pathological Anatomy.

HOSPITAL FOR EPILEPSY AND PARALYSIS, MAI VALE: OPENING OF THE NEW BUILDINGS.—The new bu ings were opened on June 13th by Her Royal Highness Princess Louise (Duchess of Argyll), accompanied by Grace the Duke of Argyll. The Princess was recei by the President, the Earl of Hardwicke, the committ and the medical staff, who were then presented. Royal Highness was afterwards conducted to one the large wards, where about 200 invited guests w assembled. The President gave a short sketch of history of the hospital from its foundation in 1866 new buildings, which with the exception of about third of the front façade are now complete, afford am accommodation for 40 beds out of the 60 which the compl building will eventually contain. The out-patient dep ment is separated by a corridor from the main building is complete in every respect. Mr. Knapp-Fisher, a mem of the committee, further supplemented the remarks of President and gave interesting details of how the neces funds for the building were obtained and what furt funds would be required to complete the building to pay working expenses. After the Princess had decla the building open the Lord Bishop of London held a sh service. The Rev. Canon Duckworth, one of the Vi Presidents, was called on to propose a vote of thanks to Princess, which was seconded by Dr. George Ogilvie, [illegible] explained that the hospital was a [illegible] of diseases of the nervous [illegible] patients came not from the immediate neighbourhood but from greater London and its outlying districts. Many also came from the provinces, Scotland, and even Ireland, so that the area from which the patients were recruited was a very large one The medical staff had therefore great opportunities for studying nervous diseases and while trying to do something to add to human knowledge and to the relief of human suffering they never forget that, "si c'est la curiosité des maladies qui fait le savant, c'est l'amour des malades qui fait le médecin." The Duke of Argyll then rose and returned thanks for the Princess in a short and humorous speech. "Prosperity to the Hospital" was proposed by the Mayor of Marylebone and seconded by Sir Henry Burdett. The inspection of the hospital then followed, when the Princess was taken over the building by the matron, Miss Oldham, the secretary, Mr. Howgrave Graham, and the architect, Mr. Keith Young.

FREEMASONRY. — *The William Harvey Royal Arch Chapter.*—On June 4th, at the Criterion Restaurant, London, this chapter was consecrated by Sir Edward Letchworth, assisted by other grand officers. It gathers its members from the various hospital lodges and judging from the successful nature of its initiation is likely to prove a great success. The three principal officers appointed were Mr. C. Vincent Cotterell, L.D.S., Mr. W. J. Walsham, F.R.C.S., and Mr. J. Ernest Lane, F.R.C.S Medical Freemasons belonging to the hospital lodges can obtain further particulars from Dr. R J. Probyn Williams, 13 Welbeck-street, W. —*[illegible]e Reine Lodge, No 2853.*—The [illegible]dge was held at the Trocadéro [illegible] 2nd. W. Bro. Amand Routh, M.D., was installed as W.M. and invested the following officers: W. Bro. John Abercrombie, M.D., as I.P.M.; Bro. [illegible] ; Bro. Victor Corbould, J.W.; [illegible], J.G.D., Chaplain; W. Bro. [illegible], P G.D., Treasurer; W. Bro Arthur E. Reade, P.M., Secretary; Bro. Jack Humphreys, S.D.; Bro. Peter Daniel, F.R.C.S., J.D.; R W. Bro. Robert Grey, P.G.W., Dir. Cer.; Bro. Victor Partridge, I G.; Bro. Hewitt Oliver and W. Bro. Francis Mellersh, P.M., Stewards. W. Bro. John Abercrombie, I.P.M., was presented with the P.M. jewel voted to him by the brethren of the lodge as a mark of their esteem and regard.

COMMEMORATION DAY AT LIVINGSTONE COLLEGE. —The commemoration day proceedings at Livingstone College took place at Leyton on June 10th. The Bishop of St. Albans presided and there were present Sir T. Fowell Buxton, Mr. T. F. Buxton, Mr. R. L. Barclay (treasurer of the College), Mrs. Bishop, Rev. J. T. Inskip (vicar of Leyton), and a number of medical men and ministers of various denominations. The Bishop of St Albans, in the course of an interesting address, said that he came there with very great pleasure to say a few words on that most interesting occasion of this commemoration. He could not help adverting first of all to the name of that college. It was a great thing to have an inspiring name and he believed that the name of Livingstone would be a perpetual inspiration. He could not but think that those who came to the college as students before going out to mission work in various parts of the world would remember and retain the permanent influence of that inspiring name. There were many advantages attached to the work of the college, one special one being the help and assistance which it gave to the missionaries in the preservation of their own health and strength in the work to which they were called. This was a feature of the college which deserved, he ventured to think, special attention. There could be little doubt that the average life of a man abroad was considerably extended when due care was taken to observe the rules of health. He had himself noticed when in India some years ago that the young soldiers who came out there and led reckless and careless lives died very soon whilst others who took ordinary care of themselves lived much longer. He had spoken to the army medical officers often on the subject, and they had told him that if the young soldier would only take real care of himself he might live in India almost as well as anywhere else. What applied to the young soldier applied also to every other Englishman living in the tropics. He was convinced that that college, which was based upon he principle that no missionary should proceed to the foreign field wit[illegible] and of the la[illegible] who realised [illegible] the missionaries who went to work abroad, and who realised further the immense advantage that was placed in the hands of those men and women who left our shores to carry the Gospel abroad and who were able to follow the Master not only in the teaching they gave to the souls but in the care they gave to the healing of the body. He was thankful that so many missionary societies had realised the value of that work and he was quite convinced that when it was thoroughly known it would receive large and munificent support.

VACCINATION GRANTS.—Mr. G. Shepley Page, public vaccinator for the Bristol district of the Bristol union, and Mr. E. J. Sheppard, public vaccinator for the Clifton district of the Bristol union, have been awarded the Local Government Board grant for successful vaccination.

GUIDES TO DEAL, FALMOUTH, AND TENBY.—For the convenience of visitors to these health resorts the town councils of the places mentioned have issued illustrated guides which can be obtained gratis by sending a post-card to the town clerks. Each guide consists of about 60 pages, printed in good type, and contains much historical information relating to places of interest. Details of excursions are also given, together with the cost of travelling, and recreations and amusements of various kinds are described. The books, which are published by the Health Resorts Development Association of St. Bride-street, Ludgate-circus, London, E C., should be useful in settling the question, "Where shall we go for a holiday?"

COMPLAINT AGAINST A PUBLIC VACCINATOR.—At the meeting of the Chippenham board of guardians held on June 8th a letter was received from the Local Government Board stating that its inspector in his report of his recent inspection of public vaccination in the Chippenham union said that the public vaccinator of Sutton Benger had as public vaccinator continued to neglect his duties, notwithstanding his written undertaking, dated March 27th, 1902, that he would in future carry out his duties in strict compliance with the requirements of the Vaccination Act. The guardians, after some discussion, eventually decided to send a copy of the letter to the public vaccinator and to ask for his observations on the same.

ORAL INSTRUCTION OF THE DEAF AND DUMB.—Earl Carrington presided at a dinner at the Hotel Cecil, on June 11th, in aid of the funds of the Association for the Oral Instruction of the Deaf and Dumb, Fitzroy-square. After the loyal toasts the chairman proposed the toast of the evening, "Prosperity to the Association," and in doing so he traced its history from the commencement. He described the visit that he had paid to the training college and practising school in Fitzroy-square and advised those present to do likewise. He referred to the work of the Royal Commission and the subsequent passing of the Elementary (Deaf and Blind) Act, 1893, and the great action the association had taken in the training of teachers for public bodies and the spread of the pure oral system. Other speakers followed and Lord Crewe proposed "The Chairman," and in doing so remarked that the association was now a national institution and ought to be supported by the public at large. The director, Mr. William Van Praagh, announced donations to the amount of £3400, including £20 from His Royal Highness the Prince of Wales.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JUNE 11TH.

Emigrants' Lodging-houses in Liverpool

MR. WEIR asked the President of the Local Government Board whether his attention had been directed to a petition signed by 125 residents and ratepayers of Great George-square, Liverpool, complaining that out of 34 houses in the square no fewer than 11 were used as common emigrant lodging houses; whether he was aware that these houses were frequented by Italians, Russian Finns, Polish Jews, Galicians, and Scandinavians, and were frequently so overcrowded as to constitute a source of danger to the public health, and that one house was found on March 25th last to contain 26 persons in excess of the licensed number and another 21 in excess; and, if so, whether he would consider the expediency of having

these facts brought under the notice of the Commission on Alien Immigration and the corporation of Liverpool, by whom these houses were let on lease.—Mr. LONG replied: The hon. Member has given me an opportunity of seeing this petition and I have communicated with the corporation on the subject. I am informed that there is no foundation for the suggestion that certain houses are frequently so overcrowded as to constitute a danger to the public health, but as I stated on
taken by the corporation in respect o
houses on March 25th last. I see no
matter before the Royal Commission on
stand that evidence has already been g
pool medical officer of health. I am informed that in all cases where complaints are made by residents in the square of emigrants' lodging-houses being a nuisance, the corporation makes inquiry and uses every endeavour to insure that the premises are used in accordance with the conditions of the lease or of any license which may have been granted by the corporation to any lessee allowing the premises to be used otherwise than as a private dwelling house.

Plague in India.

Mr. WEIR asked the Secretary of State for India whether he would state the number of persons in each province of India who had been inoculated with plague serum since this system was introduced and whether he would say how many of these persons had since died from plague.—Lord GEORGE HAMILTON replied: The returns, so far as they are available, are given in the subjoined statement:—

	Number of persons inoculated.	Number of persons inoculated who have since died from plague.
Madras	21,404	Not known.
Bengal	34,332	31
United Provinces	8,538	26
Punjab	480,737	1,158
Central Provinces	10,649	34
Coorg	3	0
Berar	2,407	9
Bombay	599,857	1,482

The Sewage Question at Walmer.

Mr. HARWOOD asked the Secretary to the Admiralty whether, seeing that the sewage from the marine barracks and hospital at Walmer is discharged crude into the sea immediately opposite the town, he would explain why the Admiralty had declined to join the authorities of the town in establishing a system of treatment for this sewage.—Mr. PRETYMAN replied: The Admiralty has not declined to join the local authorities in establishing an improved sewage system. It has for a long time past been urging them to establish such a system.

The Affairs of the Local Government Board.

The House went into Committee of Supply and on the vote for the Local Government Board for England discussed the affairs of that department.

SIR WALTER FOSTER raised the question of death certification and the need for legislation in this connexion. So loose, he said, were the law and its administration that crime constantly escaped detection. The select committee of the House of Commons of 1893 was forced to the conclusion that vastly more deaths occurred from foul play and criminal neglect than the law disco

Local Government Board whether registrars throughout the country had been warned to accept certificates only on the prescribed form so as to check the acceptance of the loose forms often sent in to notify deaths; whether any steps had been taken to induce registrars to refer uncertified deaths to the coroner; whether any steps had been taken to carry out the recommendations of the committee that in the case of uncertified deaths an abstract of the evidence at the coroner's inquest should be submitted to the registrar-general; and, lastly, what steps the right hon. gentleman, or his department, had taken to encourage local authorities to carry out local inquiries into the cause of death in all uncertified cases in their area, as was done at Manchester, Glasgow, and Edinburgh.

Dr. FARQUHARSON also spoke in favour of the amendment of the law with regard to death certification and insisted that the Local Government Board was bo rpaid.

Mr. FLOWER con aggregating large numbers
of Poor-law child where they could not be
properly supervised disease were inevitable.

Mr. CROOKS, M GORST, and several other
Members joined in

Mr. CHANNING complained of the scale of fees and charges for the administration of the Vaccination Acts, insisting that they were far too high. Before the order and circular of 1898 the cost of administration by the guardians was £72,625, but since the Act of that year the cost had been raised to £237,000. This heavy cost was felt as a grievance
in many parts of the co accination
officers were placed in an ing under
the guardians and at the from the
Local Government Boar defy the
guardians. He drew attention to the case of the Wellingborough board of guardians and their administration of the Vaccination Acts, pointing out that the total of costs incurred by vaccination officers and solicitors in 18 months amounted to £431. Up to the present time the costs had amounted to £583, or a rate equal to ¾d. in the pound throughout the district. It was a serious state of things that a vaccination officer should be er whom he
served and to impose any ratepayers.

Mr. WALTER LONG, Pre Board, said that in the case to which Mr. Channing had referred there was no doubt that the vaccination officer did incur unnecessary expense in taking legal advice whe ave dispensed with it,
but he would remind tl when this officer was
appointed he found an s of work and since he
had been in office he had done his work very well. The worst that could be alleged against him was that he had not sufficient confidence n himself. The matter, however, was to form the subject of local inquiry and therefore he would say nothing more about it now except that he had seen nothing in the case to justify him in removing officer from his position though he had indicated to him the way in which he thought he might do his work, not less successfully but at less cost to the guardians. With regard to the question of death certification he entirely agreed that it was a subject with which it would be well to deal if it were possible. He did not think the facts were quite so alarming as the hon. gentleman the Member for Ilkeston (Sir Walter Foster) would have the committee believe; but none the less the subject was a very serious one. The difficulties of dealing with the question were of a serious and practical character. The practical difficulty was that if the proposals of the Bill which was prepared in 1894 were enforced, not only would very considerable additional expense be incurred but also very considerable difficulties would probably result in the indefinite and altogether undesirable postponement of burial. The matter, however, had been engaging his attention and if he saw his way to an amendment of the law which would be practicable and would carry out what they all desired, the hon. gentleman might rely upon it that he would not fail to do his best to carry it through. As to boarding out pauper children, he confessed that he thought the barrack system had been a little hardly dealt with, but it was too late to take that view now. They were tried and were condemned, and in the case of the great Sutton schools had already been broken up. When the guardians now made proposals in dealing with their children the department never lost an opportunity of recommending them to adopt the cottage home or the boarding-out system. But the guardians were in possession of the facts of the case as well as the department and it was for them to make proposals. If those proposals appeared to depart from the principles that had been laid down the department insisted on their alteration.

Mr. KEARLEY then spoke of the administration of the Food Adulteration Acts. The figures furnished by the return of the Local G the surest way of getting effic

samples taken w ras, 34 per cent.; in Sh
ditch, 30 per cent.; and in Hackney about 36 per cent. In Manche
where the Acts had been properly administered for some years,
percentage of adulteration of milk was only 3½ per cent. That sho
what could be done by efficient administration of the Acts. The L
Government Board should appoint special inspectors to put an en
this adulteration of milk in London. If prosecution alone did not su
imprisonment should be made to follow.

Mr. PARTINGTON advocated a reduction in the medical charges
vaccination and recommended that the Local Government Board sho
supply lymph to all medical practitioners who require it.

Mr. SOARES thought that Government lymph should be supplied
private as well as public vaccinators.

Mr. SPEAR thought that on the occasion of an epidemic of small
public stations for revaccination shou

Mr. WALTER LONG said with regard
that he had been at some pains to try
of the question. There had been considerable communication
medical men on the one hand and local authorities on the other,
he had not been able to arrive at a conclusion which would justify l
in proceeding to an alteration at once. He had thought it best to
a report from a small departmental committee, after which he
posed to decide definitely what should be done. As to the suppl
lymph, he could not hold out any hope of being able to pro
lymph to private practitioners. It had to be remembered t
public vaccinators obtained their lymph for primary vacc
tion free of charge and during the recent epidemic of sm
pox the Board was able to supply them not only with
lymph for primary vaccination but also with a large propor
of what was required for seconda The dem
that the lymph should be supplied als
a very natural one but he doubted
There was the Jenner Institute in London which made
ments for the supply of lymph quite as good in quality
character as that supplied by the Government. In addition
that there were growing up over the country great laboratories
which all sorts of admirable scientific work was being car
on and in which, among other things, they were producing ly

THE NOTTINGHAM CHILDREN'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—May I be permitted to call your attention to the unfairness of the comment in THE LANCET *of May 9th (p. 1347) referring to* [illegible] March 7th last [illegible] that matters [illegible] to be in a very [illegible] intendent was adversely commented on. The facts upon which you based your opinion and comment were very fully set out, from a perfectly fair desire on your part not to express an opinion apparently unsupported by fact, and further, no doubt, to give the lady superintendent an opportunity of explaining, if she could, the facts stated, in a manner which would justify her conduct in your opinion, and in the opinion *of your readers, or of giving in a public manner her version of the* matter in order that both sides of the question might be before the public and possibly further commented on by yourselves. The article was stated to be written upon information given by me, and I quite expected that an attempt would be made in your columns on behalf of Miss du Cane to give a satisfactory explanation of her action; and I am still prepared, and indeed anxious, that this matter should receive as much public attention as possible. But in your issue of May 9th you are really unfair to me. You state in a very short note that having heard the statement of the lady superintendent on the matter you are satisfied that you unintentionally did her an injustice and that she acted in accordance with the *rules of the hospital*, but you *do* not refer in particular to one fact or circumstance laid before you by that lady upon which you have been induced to alter your opinion. I cannot help feeling that it is only necessary for me to point out the *unfairness and inadequacy of the comment in order to get it amplified* by further publication, setting out in full the statements made to you by Miss du Cane, as you had previously set out in full the statements made by me to you bearing upon the same matter. I ask for such a publication and I would also ask you to be good enough to publish this letter in order that your readers may know that I desire to adhere fully to the facts which I laid before you.

I do not feel that it would be right to say more at present than that the article in your issue o[illegible] March 7th last met with approval from many persons intimately connected with the hospital and with the facts of the case, and that it was considered a concise and accurate *statement of the true facts* and I think that many persons will be interested to know the facts and circumstances by which Miss du Cane has succeeded in justifying her action to you.

I am, Sirs, yours faithfully,

Oxford, May 30th, 1903. CHARLES E. GAITSKELL.

*** Mr. Gaitskell will see that we expressed ourselves as satisfied that the lady superintendent acted in accordance with the rules of the hospital *in certain circumstances. We do not consider ourselves* satisfied with the rules of the hospital. No answer has been made in detail to our article.—ED. L.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—A letter headed the Cancer and Skin Hospital appeared in the *Liverpool Daily Post of June 9th and I desire to say that it* was inserted without my knowledge or consent. Hoping that you will insert this disclaimer. I am, Sirs, yours faithfully,

ALEX. PAUL SWANSON, L.R.C.S. Irel., &c.,
Honorary Surgeon, Liverpool Cancer and Skin Disease Hospital.

Liverpool, June 11th, 1903.

SOME SOUTH AFRICAN ANIMAL DISEASES.

IN a paper which he has read before the Scottish Microscopical Society, Dr. G. Carrington Purvis of the Bacteriological Institute, Grahamstown, Cape Colony, said that there was probably no country in which domestic animals were liable to a greater variety of diseases than in South Africa. Some of these diseases which are peculiar, or almost peculiar, to South Africa are as follows:—Fly disease, horse sickness, heart water, red-water or Texas fever (found also in Australia and America), panting sickness ("Jag Ziekte") of the sheep, malignant malaria of the dog, catarrhal malarial fever of the sheep, and malignant jaundice of the horse. None of these diseases could be said to be infectious or contagious in any sense of the word, except perhaps the one known as "Jag Ziekte." Horse sickness occurs annually in Natal, the Transvaal, Rhodesia, and the northern parts of Cape [illegible] characterised [illegible] of the head and neck; [illegible] virulent blood [illegible] characterised by exudations into the pleura, lungs, and pericardium. When a horse has been inoculated with virulent blood there is practically nothing to note until on about the eighth day the temperature begins to rise and by the twelfth day it may be as high as 107° F. About the twelfth day the animal is distressed in its breathing, falls down, froths from its mouth and nostrils, and almost invariably dies. Dr. Purvis believes that the disease is due to a malarial parasite, which may be either extra-corpuscular or intra-corpuscular; of these forms the first is usually more or less ovoid and the second is a minute coccus. Dr. Alexander Edington of the Bacteriological Institute at Grahamstown believes, however, that the organism of the disease is a fungus. Rinderpest has been very destructive to cattle in South Africa, as in many other parts of the world; its pathogenesis is not yet definitely ascertained, but Dr. Purvis considers it to be due to a small bacterium or coccus which he has discovered. He has also devised both a curative and a prophylactic method of treating sheep for "heart-water." The former of these is, he says, similar to the one which he advocated in THE LANCET of Dec. 20th, 1890, p. 1354, for scarlet fever in the human subject.

AN EARLY OBSERVATION ON THE USE OF THE MOSQUITO NET.

A CORRESPONDENT sends us the following quotation from the *Edinburgh Review* of August, 1822, pp. 546, 547:—

> "It was lately observed casually that some persons who slept in one of these pestilential spots in Italy under a canopeum or mosquito net *escaped* the effects of the miasm, whilst those *unprovided* with this expedient took the disease" (i.e., Roman Ague or Malaria). Dr. G. Brocchi, "Dello Stato Fisico del Suolo di Roma."

Our correspondent adds that the reviewer designates it, "if true, as one of the most valuable discoveries in modern times in prophylaxis," but that the explanation "that the air breathed and expired by the sleeper acts as an antiseptic, being kept enclosed under the canopeum," is, of course, fanciful and absurd.

MEMORIAL TABLETS.

A MEMORIAL tablet, as follows, has been affixed to a new house situated in Orford-place, Norwich, now occupied by a firm of solicitors. Orford-place, it may be stated, has been rebuilt owing to the widening of the road for the electric tramway.

> "This house is the site of the residence of Sir Thomas Browne, M.D., author of Religio Medici, Vulgar Errors, and many other learned works. He lived here for about 46 years and died in 1682."

Such memorial tablets are always very interesting and we should be glad to see more of them put up by people who own or dwell in historical buildings or places.

THE UNCOVERED DUSTBIN.

THOSE who may have occasion to pass along the main streets of the City or West-end of London before nine in the morning may observe rows of uncovered dustbins standing on the curbstones like sentinels awaiting a procession. When there is a high wind not a small portion of their contents is whirled down the streets and eddies caressingly *round the garments and features of the long-suffering* pedestrian, while on warmer mornings distasteful effluvia are wafted to the nostrils of the hurrying business man who is trying to procure a few breaths of life-supporting oxygen. Those who are not obliged to reach their office, shop, or warehouse until a later hour perhaps hardly realise what advantages they have over their less fortunate brethren. We do not know why these dustbins *do not* have *covers* unless *it is that the covers* would require to be chained and padlocked to the receptacle because some people may have a fondness for annexing such trifles or else, perhaps, because the dustmen who collect the contents of the bins find it too much trouble to remove and to replace a cover. The City corporation has recently prosecuted some dustbin grubbers and proved that the City dustbins and their contents are the *property of the corporation* and that *anyone grubbing* in its dustbins is not only offending against the canons of sanitary science but is also guilty of theft from the corporation. It is hardly out of place to mention that those members of the public who have a fancy for writing to irresponsible and seductive strangers detailing their complaints should be careful of what they are doing, as we recently observed untorn letters which had blown out of an uncovered dustbin lying on the pavement outside the office of a not unknown quack.

PALMAR ECZEMA AND DYSIDROSIS.

IN the June number of the *Polyclinic* among the "Notes of Cases Demonstrated" there are some remarks on plantar and palmar eczema as compared with dysidrosis. With regard to palmar eczema it is pointed out that the diagnosis does not as a rule present any serious difficulty, since in the majority of cases chronic itching eruptions limited to this region are eczematous. It is important to reduce the thickened epidermis by the use of such means as salicylic acid or pyrogallic acid. The case of dysidrosis which was the subject of demonstration occurred in a girl, aged about 13 years, but was not typical. When she was first seen at the Victoria Hospital for Children the sides of the hands were covered with vesicles and small bullæ; these had coalesced in the palms and the greater portion of the epidermis of the palms was macerated. Under treatment with boric lotion and weak boric ointment almost constantly applied the condition had greatly improved the inflammation had subsided considerably.

EDITORIAL NOTICES.

is most important that communications relating to the orial business of THE LANCET should be addressed *usively* "TO THE EDITORS," and not in any case to any leman who may be supposed to be connected with the orial staff. It is urgently necessary that attention be n to this notice.

especially requested that early intelligence of local events aring a medical interest, or which it is desirable to bring nder the notice of the profession, may be sent direct to his office.

ures, original articles, and reports should be written on ne side of the paper only, AND WHEN ACCOMPANIED Y BLOCKS IT IS REQUESTED THAT THE NAME OF THE UTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD E WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

ers, whether intended for insertion or for private information, must be authenticated by the names and addresses of heir writers—not necessarily for publication.

annot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of [illegible] ed rates, on this or on [illegible] The Proprietors of [illegible] and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, *from the Proprietors* the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not on affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies on should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manag Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addresse

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Adv tisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

The Croonian Lectures

ON

MUSCULAR MOVEMENTS AND THEIR REPRESENTATION IN THE CENTRAL NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London

BY CHARLES E. BEEVOR, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC AND THE GREAT NORTHERN HOSPITAL.

LECTURE III.[1]

Delivered on June 16th.

MR. PRESIDENT AND GENTLEMEN,—I have not much to add about the muscles which are usually given as flexors and extensors, adductors, and rotators of the head, except with regard to the sterno-mastoids which are the chief flexors of the head and they can be seen strongly acting when a person is told to raise his head from the pillow when lying on his back, and when this is done powerfully the recti abdominis also contract to fix the sternum, as was pointed out by Winslow.[2] These two sets of muscles are associated together in certain rhythmical spasmodic contractions, as in a case which was under my care lately where a man had clonic spasm of both recti abdominis and also in both sterno-mastoids. In addition to the sterno-mastoids, the platysma myoides, the omohyoids, and the other depressors of the hyoid bone act. (I might add in passing that the depressors of the hyoid bone and the muscles between the hyoid bone and the lower jaw are well brought out when the lower jaw is opened against resistance.) With reference to extension of the head the only muscles which can be felt to contract are the clavicular part of the trapezii, the complexi splenii capitis, and probably the trachelo-mastoids.

The sterno-mastoids have been described as extensors of the head when the head is in the extreme position of extension and it is still taught in the most recent books on anatomy. Duchenne[3] also stated as the result of electrical stimulation that the sterno-mastoids "produce, on the contrary, extension of the head when it happens to be in a certain degree of reversal backwards." With this opinion I find that I cannot agree. Some time ago I made some observations on this point and I failed to find that the sterno-mastoids acted in any position as extensors of the head. To test this let the head be placed as far back in extension as it will go and then direct the person to press the head back- [illegible] tendons of the sterno-mastoids [illegible] ut if, on the contrary, flexion of [illegible] that position against resistance the tendons immediately become tense. I was therefore glad to find, which I was not aware of at the time, what Winslow[4] had stated: "The insertions of these muscles," he says, "in the posterior part of the mastoid apophyses has made some anatomists believe that they are more proper to bend the head backward than forward, their insertions being behind the condyloid articulation of the os occipitis"; but in opposition to this view he adds that "the moveable point [of the insertions] can only be determined to that part which is nearest the fleshy body and the most anterior, and consequently not situated so far back as is imagined." And on the same subject he remarks "that experiments made on dead bodies have been apt to mislead"—an opinion which I should wish to indorse.

I have no special observation to make on the ordinary muscles, but on the extraordinary muscles of respiration I should say that I have observed several cases of dyspnœa and that among the first muscles to come into action are the sterno-mastoids and as these muscles then take their fixed point from the skull the head has to be fixed by the extensors of the head. Of the other muscles I have never seen any action of the pectoralis major in dyspnœa and I think that the action which is attributed to that muscle is really performed by the pectoralis minor. This muscle could be seen acting as an inspiratory muscle in the cases which I have observed where the pectoralis major was absent. The origin of the pectoralis major from the cartilages of the ribs and the direction of its fibres are also against its having much power as an inspiratory muscle and it does not come into action till the end of a forced inspiration. Of the other extraordinary muscles the latissimus dorsi, the serratus magnus, the scaleni—though the actions of both these muscles were doubted by Winslow—and the claviculo-occipital fibres of the trapezius are the chief ones that can be observed. The serratus magnus I have observed not to be acting in one case of severe dyspnœa.

With reference to the expiratory muscles, and especially those used in such violent efforts as coughing and sneezing, I would refer to one of the muscles which is usually described as a muscle of respiration only—the latissimus dorsi. I observed a few years back that it is a powerful expiratory muscle and this is an action which anyone can prove for himself by putting the hand on the posterior fold of the axilla and on coughing a strong contraction of the latissimus dorsi will be felt. As I have already mentioned, this muscle acts also as an inspiratory muscle, using the fibres which take origin from the lower ribs to elevate them, and, therefore, it is a muscle which acts in both inspiration and expiration, a circumstance which it is rather difficult to explain. In expiration it doubtless acts by compressing the posterior part of the abdomen, in which action it is joined by [illegible] muscle which contracts in expiratory cough is the lower part of the trapezius, but whether its action is for the purpose of fixing the scapula it is difficult to say. The action of all the respiratory muscles is bilateral and their relation between the bilateral and the unilateral actions of the latissimus dorsi will be referred to later.

The time at my disposal will not permit me to say anything about the movements of the lower limb or of the ocular or facial movements. I propose therefore to leave the question of the muscles observed to take part in these different movements.

In describing the muscles which take part in any movement I have not made any mention of the action of the antagonists, and as they are considered by some authors to take a very important part in every movement it is necessary in any account of the action of muscles to consider the various views which have been held on the subject. Before considering these views, however, we must first define what [illegible] antagonists of a movement. The antagonists [illegible] move the joint in a [illegible] to this movement. This definition, or one similar to it, is so obvious that it seems hardly necessary, but in the action of closing the fingers and thumb, which, as we have already seen, is produced by the flexors of the fingers and thumb acting with the extensors of the wrist, the latter have been described as the antagonists [illegible] of the fingers and thumb. Now the movement [illegible] and thumb and the [illegible] to this is extension of the fingers and thumb, and this movement cannot be performed by the extensors of the carpus, but by the extensors of the fingers and thumb which are the true antagonists. The extensors of the carpus are synergial muscles in this movement.

The question of the part played by the antagonists in a movement has exercised men's minds from the time of Galen to the present day, and it is still a matter of controversy. According to Galen,[5] "each muscle has only a single movement which is active, it does not possess the opposite movement except accidentally. On the other hand, a muscle acts when it draws towards itself the part which is in movement, but it does not act when it is drawn to the opposite side by another muscle. ...... For each part, put into movement by the muscles as by reins, being obliged to take part in the activity of the two sides, presents in turn one of the two muscles tense and the other relaxed." It is evident from the above quotation that Galen considered that the antagonists to a movement do not contract when that particular movement is being executed. I am unable to find any other reference to the question of the antagonist till Winslow's work. Winslow[6] defined the antagonists in the following terms: "*To move any part or to keep it in a determinate position all the muscles belonging to it must coöperate*"—the italics are mine—"some of them drawing the part directly to the situation or attitude designed, some moderating this first motion by acting in a contrary direction, and others directing it laterally. The first kind of these muscles I call principal movers, the second moderators, and the third directors. The moderators in general are the same with those termed antagonists and the want of their action is in many cases supplied by the weight of the part to which they are fixed or by the additional weight or resistance of some other body." From this extract it is evident that Winslow considered that to move a part all its muscles, including the antagonists, coöperate, but he makes the important proviso that the want of their action is supplied by the weight of the part or by external resistance. This proviso limits very considerably the occasions when, according to Winslow, the antagonists act, for if they do not act when a movement is being performed against gravity or when any resistance has to be overcome the occasions are narrowed down to unopposed movements taking place in the horizontal plane where gravity cannot act. Such a movement would be that of flexion or extension of the terminal phalanges of the fingers in the horizontal direction, or of the elbow in the same plane, or of rotation of the head to the right or to the left.

---

[4] Loc. cit., section iii., p. 1075.

[5] Galen's works, De Usu Partium, part vii., book I, chapter iv., p. 331; translated by Dr Daremberg, Paris, 18[illegible]

In his Croonian lecture before the Royal Society John Hunter[7] describes the actions of muscles as immediate and secondary; the first produces immediate action of the part, the second produces the assistant, supporting and regulating actions, as in walking when the right leg moves, the muscles of the left side of the trunk act to support the whole of the left leg. On p. 262 he states that "the relaxers which become the sustainers of the muscles in action never allow themselves to relax to their full extent while the contractors are carrying on the motion of a part as it would produce weakness." The contractors, I conclude, correspond to Winslow's principal movers and the relaxers to his moderators or antagonists. If this be so Hunter evidently considered that the antagonists are never fully relaxed, but I am unable to find any expression of opinion as to whether this is modified when the movement is resisted.

Duchenne[8] is very explicit in his opinion about the action of the antagonist and he says: "In the main all voluntary movement to be executed with precision ought to be moderated by its antagonist muscles." He goes on to state that this opinion is contrary to the theory of Galen, which I have already mentioned, "and has been propagated to the present time in spite of a kind of resistance made against it by the illustrious Winslow." Duchenne quotes Winslow, but he omits the proviso of Winslow that the antagonists are excepted when any weight or assistance supplies their action. Further on in the same chapter[9] Duchenne states that he has "demonstrated experimentally that all the movements of the limbs and trunk result from a double nervous excitation by virtue of which the two orders of muscles ...... the impelling and the moderating associations are put simultaneously into action—one to produce the movements, the others to moderate them. Without ...... this entente of the antagonists the movements lose inevitably their precision and certainty." I gather from this that Duchenne's opinion is more comprehensive than Winslow's and that he considers that in all voluntary movements the antagonists take part.

On this subject of the antagonists interesting papers have been published by Beaums[10] and by Demeny.[11] The latter has made some most important observations by means of two Marey's myographs fixed on to the biceps and triceps by which tracings of these muscles under varying conditions were obtained. The conclusions which he arrived at were as follows. If static resistance is made against an effort tending to produce flexion or extension the antagonists of this movement relax. The antagonists are relaxed also during the movement every time that an external resistance acts in the way of their action whether this resistance be overcome or not by the muscles contending against it and whether these muscles shorten or elongate. In natural movements (where there is no resistance) where they are of a slow and uniform rate there is a simultaneous action of the antagonists; where the rate is variable the antagonists act as moderators of the rate and come into play a little before the movement has ceased or changed its character. Demeny's observations are therefore in confirmation of Winslow's rather than those of Duchenne. On the other hand, experiments have been made by Sherrington[11] on the action of the antagonists by electrical stimulation of the excitable cortex and he has found that in addition to contraction of the principal muscles taking part in a movement there is not only relaxation but inhibition of the tone of the antagonists of this movement. Sherrington and Hering[13] have also shown more recently the same thing by electrical stimulation of the part of the cortex where movements of flexion of the elbow were represented. They found that when the biceps contracted there was relaxation of the triceps. It therefore seems probable that the inhibitory action of the antagonists starts in the same part of the cortex and takes the same course in the pyramidal tract as the excitatory action of the principal movers. Sherrington's observations therefore agree with those of Demeny, so far as strong opposed movements are concerned. With regard to weak movements, Sherrington has informed me that even with minimal stimulation he still obtains relaxation of the antagonists; there is, therefore, apparently, a difference between the results produced by stimulating the excitable cortex in the monkey and those of making a person perform a slow unopposed movement, as the antagonists were found to be relaxed on stimulation according to Sherrington and to contract in the case of slow voluntary movement according to Demeny. From my own observations I have held that in strong movements against resistance the antagonists are always relaxed and I expressed that opinion in a paper which I wrote in 1891.[14]

This power of relaxing a group of muscles by getting the patient powerfully to contract the antagonists against resistance, I have for some time employed for clinical examination and the cases in which it is most useful are in affections about the shoulder-joint where a patient is unable to abduct the arm without the inferior angle of the scapula moving outwards at once, a sign that either the deltoid is paralysed or that it is not acting owing to painful rheumatic changes in the joint or that the joint is ankylosed. If the deltoid be contracted it can be relaxed by first passively abducting the humerus as near the horizontal line as possible and then directing the patient actively to adduct the humerus against resistance when the deltoid will be relaxed. On then again directing the patient to try to keep the arm abducted the deltoid will be felt to contract if it is not paralysed.

With regard to the question as to whether the antagonists act in all unopposed movements, as the experiments of Demeny would seem to show, I should like to point out that in the movement of rotation of the head we have an exceptional opportunity of examining the sterno-mastoid muscles, and in addition the movement of the head being in the horizontal plane there is no chance of any error from the action of gravity. Here one of the muscles is a principal mover while its fellow of the opposite side is its antagonist, so that in rotating the head with the face turned to the patient's right the left sterno-mastoid is a principal mover and the right sterno-mastoid is its antagonist. On rotating the head slowly or quickly I am unable to find either on inspection or on palpation that there is any contraction of the right sterno-mastoid; and, further, if the head be turned very quickly and be suddenly checked there is still no contraction of the right sterno-mastoid. It is quite possible that some of the other rotator muscles must act as a check to the movement, but I should say that the right sterno-mastoid certainly does not—and the muscle is so superficially situated that it would hardly be possible to escape observation. To sum up, I should myself agree with Winslow that in all movements where there is extreme resistance or where the weight of the limb has to be moved against gravity the antagonists do not act On the other hand, in the unopposed movements of rotating the head to the right, where gravity does not act, I cannot find that there is an action of the right sterno-mastoid, the antagonist to this movement; also Sherrington found by cortical stimulation that the antagonists to the resisting movement were relaxed.

[14] On Some Points in the Action of Muscles, Brain, vol. xiv., 1891.

Before leaving the question of the antagonists I should like to mention a clinical case where these muscles acted in a way which I have not seen before. It was the case of a girl, aged 18 years, who had incomplete right hemiplegia and hemianæsthesia. She had, however, no signs of organic disease and the case was considered to be one of functional or hysterical paralysis. The great point of interest about the case was that whenever she was asked to perform a certain movement the first action observed was that of the antagonist muscles. For instance, on being told to extend the elbow the first muscle observed to contract was the supinator longus, one of the antagonists to the movement of extension. This contraction of the supinator longus was followed immediately by that of the triceps and there was then a confusion with to-and-fro movements due to the alternate contraction of the extensors and flexors of the elbow. A similar thing occurred when she was told to flex the elbow; then the triceps was felt to contract first and was followed by a movement of the flexors of the elbow, and then the joint moved to and fro with much confusion. I have observed a similar condition to occur in dorso-flexing the ankle, a joint in which the typical to-and-fro hesitating confused movement is so often seen in these cases of hysterical paralysis. In another case on asking the patient to extend the knee the first contraction was felt in the flexors of the knee. In all these cases as the patient improves this symptom passes off and the joint is then moved in the normal way. This condition of the antagonists acting before the principal movers begin I have never seen in any other conditions besides those of so-called hysterical or functional paralysis. I therefore venture to think that it is a diagnostic symptom of this condition.

A muscle may take part in two different movements, as, for instance, the biceps brachii takes part with the supinator brevis in the group of muscles set apart for the movement of supination and also takes part with the brachialis anticus, supinator longus, and pronator teres in that for the performance of the movement of flexion of the forearm. It is therefore possible that if one of these movements is lost by an organic lesion of the central nervous system and not the other, the biceps which take part in both movements may be paralysed for the one movement and not for the other. I have seen cases of hemiplegia where the movement of supination was lost but not that of flexion of the elbow. Another movement which is often lost in hemiplegia when the arm is paralysed is that of elevation of the shoulder. Now the muscles which take part in the elevation of the shoulder can also, taking their fixed point from the shoulder, draw down the head and neck to that side; such muscles are the trapezius (clavicular fibres) and the levator anguli scapulæ. I have observed cases of hemiplegia where these muscles were paralysed when they acted as elevators of the shoulder but not when they acted as lateral flexors of the neck—a condition which would probably signify that the movement of elevating the shoulder was represented in a different part of the excitable cortex from that of adducting the head to that shoulder. The same thing occurs with the ocular muscles where each internal rectus can act when it takes part in conjugate movements with the external rectus of the opposite eye, but when the two internal recti act together in converging the eyes they are paralysed. Some of the above cases are instances of paralysis of a muscle for one form of unilateral action and not for another, but there is another class where a muscle may be paralysed for a unilateral movement of the arm but not when it takes part in the bilateral action of respiration.

Dr. J. Hughlings Jackson was the first to call attention to the paralysis of the clavicular fibres of the trapezius in elevating the shoulder in hemiplegia while it was still able to act as a bilateral muscle in deep inspiration. I have already described how the latissimus dorsi takes part in inspiration and expiration and that it can readily be felt to contract on coughing. The muscles of both sides here act together and, as far as I know, it is not possible for a person voluntarily to inspire or to expire as in coughing, using only the muscles of one side of the chest. Besides this bilateral movement there is the unilateral action of the muscle as an arm muscle, where it takes part in the [illegible] expiratory movement in the production of a cough or a sneeze. A cough can be produced reflexly or voluntarily, but a sneeze only reflexly, and we have therefore three conditions under which the latissimus dorsi may act, viz.:—(1) acting with the muscle of the opposite side as an expiratory muscle: (*a*) reflex coughing or sneezing, and (*b*) voluntary coughing; and (2) acting independently of the other side as an arm muscle. The next question is what will be the action of this muscle in cases of hemiplegia. I have now examined a great many cases of hemiplegia in which the arm was paralysed and in which there was complete loss of the movement of adducting the humerus to the chest wall and where consequently the action of the latissimus dorsi as an adductor was absent. Of the 12 cases which I described in my original paper in ten the lesion was presumably cerebral and probably in the internal capsule, while in two of the cases the lesion was ascertained and was in one case a tumour of the ascending frontal convolution and in the other a tumour of the centrum ovale. In all of these cases, with the exception of two, the following conditions were found. 1. In reflex coughing or sneezing the respiratory action of the latissimus dorsi was about equal on the two sides. 2. In voluntary coughing the action of the latissimus dorsi was obtained on both sides but it was frequently diminished in action or occurred later on the paralysed than on the normal side. 3. On attempted voluntary adduction of the humerus there was no action of the latissimus on the paralysed side. In two of the cases of hemiplegia where there was an exception to the general rule given above it was found that no movement was obtained on the paralysed side in voluntary coughing, but in reflex coughing or sneezing the latissimus dorsi on the paralysed side was seen to contract. A lesion, therefore, of the—let us say left—motor cortex of the internal capsule will paralyse the right latissimus dorsi as a unilateral arm muscle but will not paralyse it when it acts as a bilateral muscle of respiration reflexly and in most cases when it so acts voluntarily.

Before leaving this subject I should like to mention that this bilateral action of the latissimus is of value in diagnosing cerebral lesions from those of the spinal cord and peripheral nerves in those cases where the arm and leg of one side are involved without the face. In the case of a lesion, such as a tumour, pressing on one side of the spinal cord between the respiratory centre and the brachial enlargement, all the movements of the latissimus dorsi, including unilateral arm movement, bilateral voluntary coughing, and reflex coughing, would be lost, while in lesions above the level of the respiratory centre the reflex bilateral movement of coughing would be preserved.

Another example, but of a different kind, of paralysis of a muscle for one movement and not for another I have observed in the case of the upper or clavicular fibres of the pectoralis major. This muscle I have already referred to as one which has two actions: it acts with its lower or sternal fibres in adducting the humerus to the middle line and it also acts with the deltoid in advancing the humerus. In certain cases where the deltoid is paralysed, although the clavicular fibres of the pectoralis major can be felt to act well in conjunction with its sternal fibres in adducting the humerus, they make no attempt to advance the humerus, or when it is passively advanced to contract and to keep it in that position. The first case which I published[14] was one of paralysis after an accident and was due to lesion of the brachial plexus or of the cells of the anterior horns of the spinal cord. I have seen several other cases occurring in lesions of the cord or brachial plexus. This class of case differs from the preceding one in that we have here paralysis of a muscle for one movement and not for another, arising not from a cerebral lesion but from a lesion of the cord or the brachial plexus. This selective paralysis from a lesion of the cells of the anterior horns is in favour of the theory that these cells are arranged in a physiological rather than an anatomical manner, but as there are other reasons against this theory is it possible that there is any other explanation?

[13] On the Bilateral Action of the Latissimus Dorsi in Hemiplegia. Brit. Med Jour., Oct. 1st, 1893.

[14] Brain, vol. xiv., 1891.

Is it possible that the upper fibres of the pectoralis major which act with its lower half are not the same as those which failed to act with the paralysed deltoid? I do not think so, because there were no signs of degeneration to electrical testing in the pectoralis major and it is not probable that the same fibre should have a double nerve-supply from different parts of the brachial enlargement. Another explanation might be that when the upper fibres of the pectoralis major act with the deltoid in advancing the arm they can only do so after the deltoid has acted first and that as the deltoid does not act at all the pectoral will not start the action, but against this explanation is the observation that the weight of the arm is sufficient to bring out the action of the upper fibres of the pectoralis major and that strong resistance is not required, as in the case of the relation of the extensors of the wrist to that of the extensors of the fingers in the movement of extending the wrist described in a previous lecture. At the present time I am not able to give a definite explanation of this selective paralysis of the upper fibres of the pectoralis major.

Another question which has arisen in the examination of the actions of muscles is whether a muscle ever takes a principal or direct action in a movement which is diametrically opposed to its usual action. In considering this point it is obvious that the query could not be made in the case of a hinge joint (ginglymus) such as the elbow, as the triceps could not possibly take a direct part in the action of flexion of the elbow. It is, however, in joints like the radio-ulnar (rotatory) articulations or in ball and socket (enarthrodial) joints that it would be possible for a muscle to take part in two opposite movements. If a list is made of the muscles which are considered by anatomists to have this double action it will be found to contain the following muscles: the supinator longus, the pectoralis major clavicular fibres, the deltoid posterior fibres, and both sterno-mastoids acting together.

As I have pointed out in a previous lecture the supinator longus has been considered by many anatomists to be both a pronator and a supinator and in one of the most recent works on anatomy[17] it is stated that "the brachio-radialis (or supinator longus) assists in flexion and pronation on the one hand and in extension and supination on the other hand." This, therefore, expresses the opinion that the same muscle does take part (as a principal mover, I conclude) in two movements which are diametrically opposed to each other. With this opinion I find that I cannot agree, as from the examination of the muscle on the living subject I consider that it certainly did not take part in extension and I cannot find that it contracts in supination, its action besides flexion of the elbow-joint being perhaps very slight pronation at the end of a strong movement.

The clavicular fibres of the pectoralis major were considered by Duchenne to be both elevators and depressors of the humerus when the arm was above the horizontal line. From my observations these fibres never act in depressing the humerus, a movement which is performed by the inferior or sternal fibres of the pectoralis major.

The posterior fibres of the deltoid were considered by Duchenne to be elevators of the hanging humerus as far as an angle of 45° to the vertical, beyond which they became depressors and antagonists to the rest of the deltoid; in other words, that after an angle of 45° the posterior one-third of the deltoid suddenly changes its mind, so to say, and takes part in a movement which is diametrically opposed to the action of its previous movement. From my observations I consider that the posterior one-third of the deltoid only takes part in adduction, an opinion which I was glad to find was expressed by Richer.[18]

The last movement which I have cited is that of the two sterno-mastoids acting together. Their ordinary action is to flex the head forwards as in lifting the head from a pillow, but most anatomists describe that when the head is put back far enough these muscles act as extensors of the head. I have already expressed the opinion that I do not think that this action occurs. In cases of progressive muscular atrophy affecting the extensor muscles of the head at the back of the neck, but not the sterno-mastoids, the head falls forwards till the chin rests on the chest, due to the inability of the extensors to hold up the head against gravity, but if the patient leans far back in a chair so that the head can be allowed to extend backwards as far as it will go there will still be a slight contraction of the flexors—viz., the sterno-mastoids—to counteract gravity. Now if while in that position the patient be told to extend the head further against resistance he cannot do so owing to the paralysis of the extensors at the back of the neck, but the sterno-mastoids, so far from contracting, actually relax. There may be other muscles which may act in two opposite ways, but of those which I have cited I cannot find that any one of them takes a principal part in a movement which is diametrically opposite to its usual action.

There is, however, one muscle which certainly takes part in two opposite movements—viz., the latissimus dorsi, which contracts in both inspiration and expiration, though the action is stronger in expiration than in inspiration. I have already referred to this point and I would only say now that I think the part of the muscle arising from the three lower ribs must have a different action to the main part arising from the spine and the iliac crest. In inspiration this costal origin acts by elevating the ribs; on the other hand, in expiration these costal fibres fix the ribs and enable the external oblique muscles, whose origin interdigitates with that of the latissimus dorsi, to contract vigorously while the main part of the latissimus acts with the external oblique as a principal mover in compressing the abdominal cavity. I should, therefore, look upon the costal fibres as prime movers in inspiration and as synergic muscles in expiration. I think, therefore, that one is justified in making the statement that a muscle does not take a principal part in a movement which is diametrically opposed to its usual action, or, in other words, in two movements which are opposite in direction. I make this qualification with regard to muscles taking a principal part in a movement, as in my paper in *Brain*[19] I did not make this qualification, but I had not then noted the various muscles which act as synergic muscles in a movement. For instance, in both supination and pronation of the forearm the triceps acts to counteract the flexor action of the biceps and of the pronator terés, but as the triceps is not a principal mover in either of these movements its action would not be against the statement I have made.

Having now described the muscles which enter into and produce the movements of the different joints I propose now to say a few words about the manner in which the muscles which take part in producing any movement are associated together. In the first place do all the muscles which can take part in a movement always act whether the movement is a weak one or a strong one? I believe that in the case of a single muscle which is stimulated through its nerve physiologists hold that all the fibres of the muscle contract and that the minimum amount of work is produced not by using only some of the muscle fibres, but by using all the fibres to a slight degree of contraction, while when the maximum work is required the same fibres contract strongly.[20] The question arises whether the same principle can be applied to groups of muscles and we have to determine in producing the minimal force whether all the muscles taking part in the movement contract or only certain muscles in the group. Or, to take a simile from marine engineering, whether when a ship is travelling at half-speed all the boilers are working at half their full pressure or only half the boilers are working at full pressure.

It is not very easy to find a group of muscles the individual members of which can be examined and the order in which they take part in a movement noted. I think that the movement of supination which is effected by the supinator brevis and the biceps is one in which it is possible to ascertain how soon the biceps takes part in the movement. For this purpose, if the elbow be rested on a table and the forearm be kept in a vertical position midway between flexion and extension and at right angles to the upper arm, it will be found that the forearm can be supinated if there be no resistance without any contraction of the biceps—a point which can be ascertained by hooking the forefinger round the tendon of the biceps at the elbow. If now resistance be made to the supinating forearm the biceps will be felt to contract after the resistance has reached a certain amount. I have measured this amount and find that it comes to one pound. It therefore appears that the supinator brevis will do the work of supination when only the inertia of the bones has to be overcome, but as soon as work over one pound is required to be done the biceps is called in to help. The relation of the extensores digitorum to the extensores carpi in extending the wrist is another illustration. These two examples, I think, show that there is a definite order in which the muscles for the performance of a movement come into action.

[17] Text-book of Anatomy, edited by D. J. Cunningham, F.R.S., p. 335, 1902.

[18] Physiologie Artistique.

[19] Brain, vol. xiv., 1891, p. 57.

[20] Cf. Gotch: Journal of Physiology, Dec. 15th, 1902.

All the muscles which are grouped together for the performance of a movement do not come into action when only slight effects are required, but a certain increase of work has to be encountered before they all act. In connexion with this it is interesting to note that Sherrington[21] has found a similar condition in reflex actions, as on stimulating electrically the posterior root of the fifth cervical nerve with a Kronecke secondary coil at 15, good contraction of the supinator group was obtained in the monkey, but to evoke contemporaneous action of the biceps with the supinator a much stronger current of 90 was required.

Besides the muscles directly concerned with a movement other muscles are put into action as in performing the different movements of flexing the fingers, of flexing the fingers and thumb as in grasping, and of flexing or extending the wrist we put into action only the muscles which are directly concerned with these movements if the force exerted is slight or moderate, but if these movements are performed more powerfully other muscles are seen to join in the movement. These other muscles which are brought into the movement are the flexors and extensors of the elbow. I have therefore made some observations to ascertain which of the movements of the wrist and digits are accompanied by contraction of the flexors of the elbow, which by the extensors of the elbow, and which by both these sets of muscles. I have also measured the amount of force required to be exerted before these muscles acting on the elbow join in the movement and also to test the influence of position I have made the observations when the forearm was in the position of pronation and when in that of supination.

Table showing the Sequence of Movements in the Upper Arm to Movements of the Hand in Positions of Supination and of Pronation.

Movement performed.	Position of the forearm.	Amount of work required to be done before the triceps contracts.	Amount of work required to be done before the biceps contracts.
Fingers flexed	Supinated.	No contraction	18 pounds.
Traction at right angles to the line of the forearm	Pronated.	1½ pounds.	No contraction to 18 pounds
Fingers extended	Supinated.	4 pounds	No contraction
" "	Pronated.	No contraction	" "
Thumb extended	—	" "	—
Thumb and fingers flexed (grasping) ..	Supinated.	22 pounds.	33 pounds
Thumb and fingers flexed (grasping) ..	Pronated.	22 pounds.	40 pounds.
Wrist flexed	Supinated.	No contraction to 32 pounds.	22 pounds
" "	Pronated.	2 pounds.	No contraction.
Wrist extended	Supinated.	4 pounds.	No contraction to 24 pounds.
" "	Pronated.	No contraction	22 pounds.

[illegible] the forearm was laid flat on a table [illegible] upination, the elbow was [illegible], and the amount of work done was either registered by a dynamometer, which was grasped in the hand, or traction was made on the joints under observation by a band passed over the phalanges or the metacarpal bones and connected with a spring balance which registered the amount of work which the movement had to resist before the biceps or triceps contracted. The contraction of the biceps was ascertained by the finger hooked round its tendon near its insertion and the contraction of the triceps was easily felt by the finger and thumb placed on either side of it just above the elbow. It is to be remarked in the accompanying table of sequences that in some cases a very slight amount of resistance was able to bring out the coöperation of the triceps. For instance, in the position of pronation the triceps is called into action when the resistance to the flexion of the fingers or wrist is only from one and a half to two pounds and in the position of supination the triceps contracts when the resistance to the extension of the fingers and wrist is only four pounds. Why in the converse conditions the biceps never comes into the movement till much higher pressures are experienced is a question which further observations will be required to elucidate. First, taking the forearm in the position of supination it will be seen on looking at the table of the sequence of movements, or perhaps I should say the sequence of synergic or fixing muscles, that in flexion of the fingers, whereas the biceps contracts when the resistance to the movement of flexion amounts to about 18 pounds (8 kilogrammes) the triceps does not contract at all. Also in extension of the fingers the triceps contracts when so little resistance as four pounds (one and three-quarter kilogrammes) is experienced and no contraction of the biceps occurs even with a pressure which can overcome the extension of the fingers These observations show that in the supinated position of the forearm flexion of the fingers, when opposed, is followed by contraction of the biceps, and extension of the fingers, when opposed, is accompanied by contraction of the triceps. Secondly, that in grasping with the fingers and thumb, which, as we have seen in a previous lecture, is performed by the flexors of the thumb and fingers and the extensors of the wrist, the contraction of both the biceps and triceps occurs but that of the triceps first. Thirdly, in extension of the thumb only, a movement which would probably not affect the elbow-joint, I could not discover any contraction of the biceps or triceps; in other words, the muscles producing flexion or extension of the elbow are brought into a movement which is in the direction of flexion or extension respectively or to counteract the tendency of the resistance to move the elbow in the opposite direction, but in a movement like grasping, which is not in the direction of flexion or extension, both sets of muscles (triceps and biceps) contract and the elbow is kept fixed. That this sequence is very much due to position is shown by the opposite results which were obtained according as the forearm was pronated or supinated. For instance, in flexion of the fingers or of the wrist in the supinated position the biceps contracted at 18 pounds and 22 pounds respectively but not at all in the pronated position This is probably because when the fingers or wrist is flexed against resistance with the forearm supinated the opposition to movement of flexion of the fingers or wrist is in the direction of extension of the elbow and the biceps contracts so as to prevent the elbow being extended when the pressure on the wrist or finger reaches a certain amount. But when the forearm is in the pronated position the conditions are reversed; the direction of the opposition to the flexion of the wrist is now in the direction of flexion of the elbow and to prevent the elbow being flexed it is now the triceps which contracts and not the biceps.

To elucidate still further the question of position I have made experiments on the movement of grasping with the fingers and thumb: (1) with the forearm resting free on a flat surface and (2) with the forearm fixed immoveably on a flat surface. It will be seen on looking at the table of sequences that in the movement of grasping the contraction of the triceps occurs sooner than that of the biceps. As there was evidently some disturbance of the position of the elbow which necessitated contraction of the triceps before that of the biceps the forearm was fixed to prevent any movement of the elbow. In the position of supination, whereas with the forearm resting freely the triceps contracted when the grasp registered 24 pounds, with the forearm fixed it did not contract till the grasp was almost doubled—i.e., 45 pounds. In the position of pronation with the forearm free the triceps contracted when the grasp was 13 pounds and with the forearm fixed at 29 pounds. The same conditions were obtained when the forearm was in the mid-position between supination and pronation. The contraction of the biceps was not influenced by the position of the forearm being free or fixed. These observations show that the contraction of the triceps [illegible] some action of flexion of the elbow [illegible] asping and on carefully [illegible] when the forearm rested [illegible] of flexion of the elbow was seen. I have measured the force of this flexion of the elbow by a band round the lower end of the forearm, which was attached to a fixed point with a spring balance interposed, and I find that the force exerted by the elbow in grasping amounts to one pound. I have also ascertained that it makes no difference whether the grasp is 29 pounds or the maximum is 54 pounds, as the amount of force produced by this slight flexion of the elbow is in both cases one pound. This would mean that in the supinated position whatever the strength of the grasp the triceps so adapts itself that it will not permit flexion of the elbow of more strength than one pound.

---

[21] Transactions of the Philosophical Society, Series B, vol. cxc., 1898, p 154

Another question which arises is, Why in the supinated position does the triceps not coöperate till the grasp has reached 24 pounds, whereas in the pronated position it takes part in the movement when the grasp has reached 13 pounds and in the mid-position at 20 pounds between the two other fingers? It must mean that in the position of pronation the forearm muscles produce flexion of the elbow sooner than in the position of supination and therefore that the triceps must intervene sooner to prevent flexion of the elbow. If this be true it is in harmony with what was stated in a previous lecture that patients who have lost their proper flexion of the elbow manage to flex this joint by first putting the forearm into the position of pronation.

LECTURE IV.

Delivered on June 18th.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I described that in the movements of the wrist and fingers, when they were performed powerfully, there was contraction of the muscles acting on the elbow-joint either of the biceps or the triceps or of both. And I pointed out that in flexing of the fingers and wrist the biceps contracted and in extending the fingers and wrist the triceps contracted, while in closing the fist the triceps acted first, followed by the biceps. The fixation action of muscles was described by John Hunter in his Croonian Lectures on Muscular Motion delivered before the Royal Society in 1777,[22] where he stated that "there is in every animal, therefore, a fixed point from which the parts of the body take their principal motions. In the human body this fixed point seems to be in the joints of the thigh bones, which point being in the middle of the body must be common to the extremities. ...... Besides this there are many fixed points, so that the body is to be looked upon as a chain of joints whose general centre of motion is in the joints of the thighs." Now this centre of motion corresponds to the point of centre of gravity described by subsequent observers. This position of a fixed point depends on the attitude of the person and the place where his body comes in contact with the ground and where it gets a firm foundation, as, for instance, if a person advances the upper limb when lying on his back on the ground the fixed point will be the cervicodorsal spine; if he perform the same movement sitting on a chair the fixed point will be the pelvis; if, however, the same movement be performed in the erect posture the fixed point will be where the soles of the feet come in contact with the firm ground. We therefore, it seems to me, have to differentiate in any movement between the muscles which take part directly in that movement and the muscles which are used to fix the joints which lie between the joint which is actively engaged and the fixed point or base on which the structure works, and again these fixing muscles have to be separated into those which always take part in the strong movements irrespectively of the posture of the person which we may call *essential* and those which depend on the position of the person and where his fixed point or base is, which we may call *postural.*

As an example of the essential muscles we may take the contraction of the triceps and biceps which accompany the movements of the hand and which I have just described, and as an example of the postural muscles the contraction of the erector spinæ when the upper limb of the opposite side is advanced or abducted and which, as I showed in a former lecture, only contract in certain positions of the spine to prevent the equilibrium being disturbed. I should therefore describe the muscles taking part in any one movement as: (*a*) prime movers; (*b*) synergic muscles; (*c*) fixation muscles: (1) indispensable or essential and (2) postural; and (*d*) antagonist muscles in occasional movements. I take as an example the movement of grasping an object or closing the fist. Here the prime movers are the flexors digitorum and flexor pollicis and small thumb muscles. The synergic muscles are the extensores carpi and the essential fixation muscles are the triceps and biceps. Another example is the movement of advancing the humerus. Here the prime movers are the deltoid anterior fibres, pectoralis major superior fibres, biceps; the synergic muscle triceps (outer and inner heads) which come into play to counteract the flexor action of the biceps; the fixation muscles: (1) essential, trapezius, and (2) postural, erectores spinæ. The principal or prime movers are the muscles which directly produce the action required and are called by some authors the antagonists; the synergics are the muscles which, as I have previously stated, are brought into the combination when a prime mover has, by passing over two or more joints, two or more actions of which only one is required and the synergics are the muscles which neutralise these undesired actions; they are represented in the first example given above by the extensores carpi. The fixation muscles, as I have already described them, are: (1) those which are essential to the movement in all postures and which are not influenced by the position of the person; and (2) those which only act to prevent the equilibrium of the trunk being disturbed by the movement and which I have therefore called postural. The antagonists produce the movement which is diametrically opposed to that of the prime movers. Before proceeding to describe the relation of these different classes of muscles to each other I must refer to the classifications of previous observers.

According to Winslow,[23] the muscles may be divided into: (*a*) principal movers; (*b*) moderators or antagonists; and (*c*) directors or collateral muscles which are wanting in hinge-joints (ginglymus), and as an illustration he cites[24] the muscles employed in standing where the principal movers are the gastrocnemii and soleus; the moderators are the tibialis anticus and peroneus medius and minimus; and the directors are the tibialis posticus and peroneus maximus. Winslow does not mention the action of the synergics—i.e., the action of the extensors of the wrist in the movement of closing the fist—but he states that the extensor digitorum moderates the flexion of the fingers in all the determinate degrees of action. Duchenne[25] divides the muscles into: (*a*) associations musculaires impulsives; and (*b*) associations musculaires antagonistes: (1) associations musculaires moderatrices, and (2) associations musculaires collaterales. He includes under (*a*) the synergic muscles as well as the principal movers, so that in the movement of extending the finger, which he gives as an example, he enumerates the extensor digitorum and the interossei and lumbricales and the synergic muscles, the flexor carpi, as being included in group *a*. As an example of the action of the antagonists Duchenne takes the movements of the vertebro-cranial column presiding over the erect position and states that we must consider two kinds of principal phenomena: (1) the muscular association which produces its extension; and (2) the harmony of the antagonistic muscles, which moderate and assure this extension and the normal attitude of the spine. The erectores spinæ form the muscular associations producing extension of the spine and Duchenne goes on to say that "on the harmony of the antagonist muscles or rather on the degree of force of the muscles moderating the extension or flexion of the spine depend necessarily the different degrees of the lumbo-sacral curves." He also cites as collaterals in the same position of standing the lateral movers of the vertebral spine, the quadratus lumborum to prevent the trunk inclining to one side or the other. This illustration which Duchenne gives—viz., the muscles of the vertebro-cranial column during the vertical position—does not to my mind touch the question of the action of the antagonists and the collaterals, and the same objection applies to Winslow's statement about the tibialis anticus and peronei being antagonists to the calf muscles in standing. According to my observations the flexors and extensors of the ankle and the flexors and extensors of the spine are not acting in antagonism to each other, but each in turn contracts as a prime mover to counteract and to rectify the displacing movements due to gravity and according as this displacement is forwards, backwards, or lateral the erectores spinæ, the recti abdominis, and the lateral movers of the spine respectively on the side opposite to the movement contract. It is, of course, possible to throw all the muscles of the leg into a static contraction so as to convert the leg into a rigid pillar, as in skating a large edge, but here no movement of any joint is taking place and it would not be possible to say which muscles are the prime movers and which are the antagonists, they are all probably prime movers.

[22] The Works of John Hunter, F.R.S., edited by James F. Palmer p. 245. 1837

[23] Winslow: loc cit., p. 159.

[24] Loc. cit., p. 332.

[25] Loc. cit., p. 676, et seq

John Hunter[26] states in his Croonian lectures that there is no one known muscle in the body that we can throw into [illegible] independently of the collateral effects [illegible] expressed the opinion that partial [illegible] not exist in nature, that they are [illegible] by means of faradisation, and Dr. Hughlings Jackson has laid down that "nervous centres know nothing of muscles, they only know of movements." This in other words means that the ordinary individual has no power to make any one muscle contract by itself; he can only order a movement, he cannot pick one muscle out of a group and order that to contract; he can, on requiring to attain a certain object, order a certain movement, but the mechanism by which that movement is produced and the muscles which are required to perform that movement and the order in which they act is not known to the brain, the order for a movement is given and the movement is performed. Take the following example to which I have referred in a previous lecture. In extending the wrist by means of the extensors of the fingers against resistance the muscles come into action in a definite order which apparently cannot be altered. At first the prime movers are the extensors of the fingers and the interossei and the synergic muscles are the flexors of the carpus; later, if the resistance be increased at a certain point, the extensores carpi come to the assistance of the extensores digitorum, but apparently the individual has no power to make the extensores carpi contract before the pressure has reached the required amount. This, as I have already shown, is well exemplified in lead paralysis of the extensors of the fingers. Here, although the extensores carpi are not affected, the individual is unable to put them into action because it is not their place to extend the wrist with the fingers straight when this movement is begun by the extensores digitorum until the strain to be overcome reaches a certain amount. Another example of the intimate association between the principal movers and the synergic muscles is in the extension of the thumb. Here the extensors of the thumb are the prime movers and the extensor and flexor carpi ulnares are the synergic muscles and it is quite impossible to extend the thumb in the slightest degree and in any position of the wrist without contracting these muscles, and if the extensors of the thumb are paralysed by a peripheral lesion the wrist is adducted to the ulnar side.

Now, although the use of the ulnar muscles is doubtless to counteract the abductor action on the wrist of the extensor ossis metacarpi the contraction of the ulnar muscles is not dependent on the displacement of the wrist, for it takes place even if the thumb be extended [illegible] wrist has been passively abducted to its full extent so that there is no chance of the wrist being further abducted and consequently there is no necessity for the ulnar muscles to contract. We can only therefore conclude that the two sets of muscles are so intimately associated in this movement of extending the thumb that they act together in all positions of the wrist, and when one of the group is paralysed by a peripheral lesion the other set of muscles goes on acting as the innervation from the brain passes down, just as if the whole complex could be thrown into action. As, however, one group is paralysed the movement occurs only in the other group, showing that they are a true synergic combination. It seems, therefore, than an individual has no power voluntarily to leave a muscle out of a combination to which it belongs. Another question is, Is it possible voluntarily to add to the list of muscles which are told off for a certain movement or to supplement them when one is paralysed? For instance, it has been said that the anterior portion of the deltoid can replace part of the functions of the pectoralis major, but it must be remembered that the only function to which this could refer would be the action of advancing or adducting the humerus, but the deltoid is naturally associated with the clavicular part of the pector[illegible] the other; on the other hand, when the muscles proper to the movement are paralysed the difficulty may be overcome by a series of *other movements*. I remember seeing a case with paralysis of the flexors of the elbow in a man who managed to produce flexion of the elbow by advancing the humerus, rotating it out, and by this means letting the forearm be flexed by gravity, but here the muscles were not supplemented by other muscles but an entirely different group was thrown into action by which the desired change of position was obtained. I think, therefore, that although by exercise and training it may be possible to alter the arrangement of the muscles taking part in any movement, the inability of a patient with lead paralysis to induce the extensores carpi to act out of their proper order is against this possibility. By mechanical means, such as transplantation of tendons, first recommended by Nicalodoni[28] in 1882, it is possible to take a muscle out of one group and to put it into another and I have had the opportunity of seeing the results of some of these cases under the care of Mr. E. Muirhead Little[29] and Mr. [illegible] Orthopædic Hospital.

[illegible] above statements I think that [illegible] for every voluntary movement there is a definite number of muscles, usually two or more, which come into action in a definite order which cannot be altered and the individual members of which cannot be omitted and cannot be supplemented except perhaps by long training and exercise or by operative procedure. It will thus be seen that in every voluntary movement there must take part a minimal number of muscles below which it is not possible to go. This combination of muscles I would call the ultimate or the minimal components of a movement. Such ultimate components of the movement of extending the metacarpal bone of the thumb are the extensor ossis metacarpi pollicis, the extensor carpi ulnaris, and further on in the movement the flexor carpi ulnaris, and in the movement of extending the first phalanges of the fingers the extensores digitorum and the flexores carpi. Where in the central nervous system are these ultimate components of a movement represented? There are three places where they may be represented—in the spinal cord corresponding to Dr. Jackson's lowest level in the cerebral excitable cortex, or so-called motor area (Dr. Jackson's middle level), or in the centres postulated to preside over the so-called motor area (Dr. Jackson's highest level). With regard to the last place I have no evidence to offer at present. Representation in the spinal cord of the different muscles of the limbs has been studied both experimentally and clinically and the first question that has to be answered is whether the grouping of the cells of the anterior horns of the spinal cord is of a morphological or a physiological type. In other words, whether in the brachial enlargement the cells which supply the muscles forming the ultimate components of any one movement, as that of extending the thumb (such as the extensors of the thumb and the ulnar flexor and extensor of the carpus), are aggregated together, so that a lesion in that particular place would cause paralysis of this movement only.

I do not propose, and I have not the time, to describe all the numerous observations which have been made, but experimentally the chief ones have been done on the roots entering into the brachial and lumbo-sacral plexuses by Müller, Van Deen, and Panizza on frogs, by Peyer and Krause on the rabbit, by Risien Russell on the dog, and by Ferrier and Yeo, Forgues and Sherrington on the monkey. Anatomically the question has been worked out by Herringham and Paterson by dissection and clinically by [illegible] and many others. I also myself read a paper [illegible] Chirurgical Society in 1885 [illegible] in the spinal cord where I [illegible] with affection of the lower half of the pectoralis major, the triceps, and the latissimus dorsi only and other papers on brachial plexus paralysis.

Opinions have differed as to whether the arrangement of the cells in the anterior cornua is anatomical or physiological. The arrangement of the cells in the anterior horns and also of the cords of the brachial plexus in a physiological order is supported by a condition which I have observed and which I have already referred to—viz., the paralysis of the pectoralis major (clavicular fibres) for one class of movements but not for another. In lesions of the anterior horns and of the brachial plexus, especially of the fifth cervical root, the deltoid is paralysed, and in passively advancing the humerus it will be seen that along with paralysis of the deltoid the clavicular fibres of the pectoralis major do not make any attempt to contract when the patient makes an effort to keep the humerus advanced. On the other hand, if the patient be directed horizontally to adduct the clavicular fibres will contract in combination with the sternal fibres of the pectoralis major. The paralysis of a muscle from a lesion of a particular part of the anterior horns of the cord when it is associated with one set of muscles and not of the same muscle when it is associated with another set in a different movement would show that the anterior cornual cells had the power of grouping muscles together for a functional purpose. Against the view that each root of the plexus—and therefore presumably the segment of the cord from which it comes—when stimulated produces a well-coördinated movement by groups of muscles acting synergically is the statement of Herringham[31] that although both pronators must act together in one movement the pronator quadratus is supplied by one root and the pronator teres by a different root. The cells supplying a single muscle in the limbs extend over two or more segments. Also no segmental grouping of any of the cell columns of the spinal cord has been detected[32] and this conclusion stands in harmony with the results of the examination of the relation of the reflex movements to spinal segments.

On the whole the evidence is against the cells of the anterior cornua being arranged physiologically for a functional purpose. But although the anterior cornual cells are probably not arranged for functional purposes it does not follow that there is no power of coördination in the spinal cord. This is proved by the various complicated reflex actions which are performed when the spinal cord is cut off from the cerebral influence, reflex actions which as in the plantar reflex are made up of contractions of several joints in the limb. It has been found by Page May[33] and by Sherrington[34] that electrical stimulation of each posterior root produces a definite movement which acts reflexly through the anterior cornual cells. Sherrington also states that the group of cells discharged by spinal reflex action innervate synergic and not antagonist muscles. May's observations on the lumbar enlargement of the monkey and Sherrington's[35] observations on the brachial enlargement are of interest here. May's observations were also made by direct excitation of the spinal cord along the postero-external column: "The movements resulting from excitation of a segment of the spinal cord in the lumbo-sacral region and those from excitation of the corresponding posterior root are similar but are never quite identical. In each case flexion is the predominating effect but in the former case (spinal cord) the resulting movements are always stronger than in the latter (posterior root) and frequently movements in other parts (tail, perineum, &c.) are added." The stimulation of one posterior root causes impulses to pass out along many anterior roots, and while stimulation of the posterior roots always produced flexion, that of the anterior roots produced extension. Sherrington gives a list of the movements obtained by stimulation of all the posterior roots in the monkey, but as his results in the lumbo-sacral cord correspond very closely with those of May, I have given his observations on the brachial part of the cord only. The resulting movements obtained by Sherrington from stimulating a posterior root are synergic and not antagonistic which, as Sherrington remarks, is against the theory of the action of the antagonists which we have already discussed.

Besides the movements obtained by stimulating a posterior spinal root, are the results obtained by Sherrington[36] on the isolated length of the brachial enlargement on stimulating the skin of the palm of the hand; the reflex movements obtained were as follows: Thumb—flexion, adduction; shoulder—retraction, later protraction; wrist—extension; elbow—flexion; and fingers—flexion. It is therefore evident that even in the highest animals, as the monkey, it is possible to evoke such highly coördinated movements as the above. The mechanism by which this is effected is by the afferent fibres of the posterior root which either sends branches forwards in the grey matter of the spinal cord to the neighbourhood of the cells of the anterior horns or the cells of the posterior cornua are interposed between the posterior root fibres and the anterior cornual cells. Whether for the purposes of producing such coördinated movements as those obtained by stimulating the palmar surface the two-cell system is sufficient it is difficult to say, but it has been suggested[37] that the two cells are probably connected by the help of a mediate system of cells. The time at my disposal will not permit me to go into this question, but there is evidently in the cord itself a nervous organisation which can produce coördinated movements reflexly on stimulating the skin or the posterior spinal roots, but whether the coördination is the same as that occurring in voluntary movements it is difficult to say. I should mention that Professor Gad[38] was the first to ascribe to the posterior cornual ganglion cells in the frog the function of connecting together the cells for the flexors of the ankle, the knee, and the hip.

The representation of movements in the excitable area of the cortex cerebri next claims our attention. Time will not permit me to enumerate the various observers from the pioneers—Hitzig and Ferrier—to the present day, nor is it my intention to discuss the much vexed question whether the so-called motor, or, as it is better to call them, the excitable areas, of the cortex are motor, sensori-motor, or sensory. But that they depend on sensory impressions for the power of exciting movements is shown by the remarkable observations of Mott and Sherrington[39] who found that after dividing all the *posterior* spinal roots of the brachial enlargement of the cord the voluntary movement of grasping by the hand was permanently lost, while movements of the limb could be elicited with apparently normal facility by electrical stimulation of the part of the cortex where the movements of the upper limb are represented.

I wish particularly to refer to the results obtained by Sir Victor Horsley and myself on stimulation of the excitable cortex in the monkey[40] and the orang.[41] In the monkey we examined every two square millimetres of the excitable cortex, and we found in certain squares where the upper limb was represented that the coördinated movements of flexion of the fingers and thumb, extension of the wrist, and flexion of the elbow was obtained, and though flexion of the fingers and flexion of the wrist were also obtained in other parts of the cortex flexion of the thumb and fingers and extension of the wrist were much more frequently the rule. Another coördinated movement which was obtained was that of opening the eyes and simultaneous turning of the head and eyes to the opposite side, a combination described previously by Ferrier. The movements obtained from stimulating the excitable area of the cortex are always coördinated movements and never those of single muscles unless a movement was performed by a single muscle. The frequent association of the extensors of the wrist with the flexors of the fingers was sufficiently frequent to warrant the opinion that a synergic association existed between those two sets of muscles. The results which Sir Victor Horsley and myself obtained from our experiment of stimulating experimentally the cortex in the orang 13 years ago have been in the main confirmed by the more extensive researches of Sherrington and Grünbaum[42] who have added to the number of movements which we had found to be represented in the excitable cortex. In the one case which we examined the representation of movements was found chiefly in the ascending frontal convolution, but we also obtained movements of the index finger, of the thumb, of the orbicularis oris, of elevation of the upper lip, and of pouting of both lips from stimulation of the ascending parietal convolution. Sherrington and Grünbaum, however, failed to get any evidence that any movement was represented in the ascending parietal convolution. In the orang the movements that we obtained were nearly always single movements, such as flexion of the elbow, flexion or extension of the thumb, and they differed from those obtained in the monkey in that the sequence of movements occurring from stimulating one spot which Dr. Hughlings Jackson has termed the "march" was rarely obtained. The best example of this sequence of movements which we obtained in the orang was the movement of opening the eyes, followed by that of turning the eyes to the opposite side and ending with the movement of turning the head to that side. Professor Sherrington has been good enough to inform me that they did obtain in the experiments sequence of movements, including the combination of flexion of the fingers and thumb with extension of the wrist, and though they agree with us that the representation of the movements in the excitable cortex of the anthropoid apes is much more differentiated than in that of the monkey, they did obtain evidence of the representation there of such coördinated movements as that of grasping. The coördinated representation of muscles for a definite movement which was found to exist in the excitable cortex of the monkey is also found in the internal capsule according to the investigations by Sir Victor Horsley and myself.[43] In these experiments the internal capsule was cut across horizontally and every square millimetre of its fibres was stimulated electrically. *In almost every one of the experiments*—which were 45 in number—the movements were obtained from one square of flexion of the thumb and fingers and extension of the wrist and frequently flexion of the elbow and adduction of the shoulder. The association between the flexion of the thumb and fingers and the extension of the wrists was most marked and occurs so often that the association must be for a synergic purpose. The association between the flexors of the fingers and the extensors of the wrist has been well shown by some interesting experiments by Hering,[44] who stimulated electrically the cortex in the monkey about one millimetre above the angle of the precentral sulcus, where Ferrier and Horsley and Schäfer had produced the movements of closing the hand into a fist and where Sir Victor Horsley and myself[45] had found flexion of the fingers and extension of the wrist. Hering first stimulated this part and produced the characteristic closure of the fist. He then cut through the tendons of the extensores carpi radialis longus et brevis and he then obtained not only flexion of the fingers but also flexion of the wrist owing to the absence of the synergic action of the extensores carpi radiales. Also, when in place of dividing the tendons of the extensors of the wrist he divided the tendons of the flexors of the fingers the wrist was extended, but the fingers were not flexed when the same part of the cortex was stimulated. Hering also performed the same experiment and got the same results by stimulation on the horizontally cut surface of the internal capsule, the fibres of which we had found to give flexion of the fingers and thumb and extension of the wrist. These experiments are very strong evidence that coördination of synergic movements take place in the excitable area of the cortex.

We have now considered the question of representation of the ultimate components of a movement in the spinal cord and in the excitable cortex. What, then, is the relation between these two parts of the nervous system? We have seen that there is in the grey matter of the spinal cord a mechanism by which on stimulation of the posterior root fibres a series of coördinated movements are produced and that it is also possible in the excitable cortex to produce coördinated synergic movements. The questions are: Does the coördination of the simple voluntary movements take place in the spinal cord or in the excitable cerebral cortex only? if in the cord, is there a mechanism there which is put into action by an impulse from the excitable cortex travelling down the pyramidal tract? if there be a mechanism in the cord for receiving cortical impulses, is it identical with that for receiving reflex impulses from the skin for the production of reflex actions? lastly, if all the coördination of simple movements takes place in the excitable cortex—between which and the muscles there is no intermediate coördinating station—then is the mechanism in the spinal cord used solely for reflex actions? In speaking of the relation between the representation of simple movements in the cord and in the cortex I would ask: Can all the reflex movements which can be elicited by stimulation of the posterior roots or of the skin be reproduced voluntarily? It is well known that certain reflexes, such as coughing, can be performed voluntarily and can be inhibited and prevented from taking place, while others, like sneezing, cannot be voluntarily performed and cannot be inhibited, but with regard to the skin reflexes I do not know that the question has been raised and it occurred to me to try to *reproduce them voluntarily*. The plantar reflex can, I think, be reproduced voluntarily, though I am not sure that the order in which the muscles contract can be exactly imitated. The cremasteric cannot be reproduced voluntarily. The abdominal and epigastric reflexes in which the middle line with the umbilicus is drawn to one side reflexly by scratching with a quill pen along the side of the abdomen I was surprised to find that it was quite impossible to reproduce voluntarily.

My time is too short to go into the question whether some of these superficial reflexes are spinal or cerebral[46] in origin and why they are frequently lost in hemiplegia, but assuming that they are spinal we have coördinated movements produced reflexly by stimulating the skin and which cannot ordinarily be reproduced by voluntary effort. The fact that an ordinary [illegible] sented in the cord but was not represented also in the excitable cortex, or that if the movements obtained by exciting the cortex were also represented in the spinal cord the mechanism by which these movements were coördinated is not the same as that by which the cutaneous reflexes were brought about. At present I do not think that we are in the position to answer this question whether these reflexes are of cerebral or spinal origin, and in view of the inability to reproduce voluntarily all the cutaneous reflexes the question will have to be worked out, supposing that the movements obtained by stimulating the cortex are also coördinated in the spinal cord, whether the mechanism in the cord used for cortical impulses is identical with that used for coördinating the movements obtained reflexly by irritating the skin.

I will now pass to the relation of the excitable cortex with the coördination of simple movements. The relation of the excitable cortex to the coördination of simple movements has been discussed by various authors, but the time at my disposal will not allow me to go into the history of the subject. As some authors have raised the question whether single muscles can be put into action by a cortical pyramidal cell I may say at once that this is a condition which I believe never occurs except there be a movement in which only one muscle takes part. The results obtained by stimulation experiments and also by clinical observation of epileptic attacks and of hemiplegia due to lesions of the cortex or of the internal capsule are all in favour of the view that movements and not single muscles are represented in the arrangement of the cortical cells and of the fibres forming the internal capsule. This is the doctrine taught by Dr. Hughlings Jackson. As I therefore consider that only coördinated [illegible] are represented in the excitable cortex I will [illegible] a case which I have lately [illegible] through the kindness of Mr. J. R. Lunn. It was that of a man with recent hemiplegia—*and here in passing I would remark that I do not think much* can be learnt with regard to coördination from old cases of hemiplegia who have recovered one or two movements but in whom there are probably secondary changes in the spinal cord. In describing this case I would *remind you of what I* said in a previous lecture, that in strong movements of grasping the prime movers are the flexors of the thumb and fingers, the synergic muscles, the extensors of the carpus, and the fixation muscles, the triceps, followed by the biceps. The case was a patient suffering from hemiplegia in whom, contrary to the usual course, the return of power had commenced in the hand, and he could perform the movement of grasping, but he had no power to extend the wrist or to flex or to extend the elbow. On getting this patient to grasp with his full strength I noted that in addition to the contraction of the flexors of the thumb and fingers there was a contraction of the synergic muscles of extending the carpus and of the fixation muscle, the triceps, and that the action of the triceps was not felt to contract till a certain strength of grasp was reached. The important point is that the patient had not the slightest power to contract the extensors of the carpus when he was told to perform the movement of extending the wrist or of the triceps when he was told to extend the elbow. In this case where the lesion was probably in the internal capsule, the only fibres which were available for impulses emanating from the "arm-centre" of the cortex were those coming from that part, where the movements of grasping were *coördinated*, whereas the *fibres conducting impulses* emanating from the part of the cortex where extension of the wrist and extension of the elbow were represented were unable to pass. In other words, the patient could put into action the extensores carpi and the triceps when they form part of the movement of grasping, but he could not make either of them contract as prime movers in extension of the wrist or elbow. The next point is, Is the link between these three sets of muscles in the cord or in the cortex? Starting from the muscles and following up the motor nerves, where is the first station where the arrangement of cells is to be found by which these three sets of muscles work together? Is it in the spinal cord or in the cortex? If it be in the cortex it would mean that there must be *three sets of cells which would be coördinated* to act together for this purpose; it would also mean that there must be separate cells for the movements of the extensors of the wrist and of the elbow for their action as prime movers and separate cells for all the different combinations. Though the cortex might be large enough to contain all these cells it would be impossible to find room in the internal capsule and much less in the pyramidal tract for all the fibres that would be required. On the other hand, these three sets of muscles might be joined together under the guidance of cells in the posterior cornu and the combination would be thrown into action by one impulse from the cortex. I think that the question is best approached by examining what takes place in the movement of lateral deviation of the eyes. If the cortex in the angle of the præcentral sulcus of, let us say, the left side be stimulated, both eyes move conjugately to the right, and if the particular fibres of the left internal capsule be stimulated the same effect is produced and conversely if the cortex or the capsule be paralysed the eyes deviate to the left. These fibres passing through the left internal capsule and the crus cerebri cross to the opposite side to the nucleus of the right sixth nerve, whence fibres pass over to the part of the left third nucleus, or third nerve, which presides over the left internal rectus muscle. In this case the link between the right external rectus and the left internal rectus takes place in the medulla in the sixth nucleus, as suggested by Foville. The proof of this is that in lesions of the right sixth nucleus, without involving the third nuclei or the pyramidal tract, the same conjugate paralysis of the eyes, with deviation to the left, is produced as from a lesion of the left cortex. Now, although these two muscles, the external and internal recti, are on opposite sides of the body this conjugate movement of the eyes is as much a unilateral movement[47] as that of closing the fist, for the reason that on stimulation of the left cortex the eyes turn always to the right and not to the left. I think therefore that we are *justified in inferring that the principle which underlies the* simple movement of turning the eyes to the right can also be applied to the simple movement of closing the fist and that the link between the three sets of muscles, the flexors of the fingers and thumb, the extensors of the carpus, and the triceps, takes place somewhere below the level of the internal capsule and by analogy in the spinal cord.

It has been shown by von Monakow[48] and by Schäfer[49] that the ending of the fibres of the pyramidal tract is in the neighbourhood of the posterior horns and not in the anterior horns, as was formerly thought to be the case. Von Monakow also thinks that there are intermediate cells between the anterior cornual cell and the ending of the pyramidal fibre and that this cell has the power to bring out associated movements. It therefore seems probable that the coördination or the link between the muscles entering into a simple movement takes place in the cells of the posterior cornua which are put into action by impulses coming down the pyramidal tract from the excitable cortex where these movements are represented. Whether the same coördinating mechanism in the spinal cord is used alike for reflex actions as well as for cortical impulses or whether there is a separate mechanism for each I do not think, as I said before, that we can give a certain answer. Now, as the most complicated and intricate muscular performances are only an arrangement of simple movements in some particular order it is probable that in learning some new *combination of movements, such as playing* the violin, fencing, or golfing, the simple movements represented in the excitable cortex are in response to visual or auditory impressions brought into action in their proper combination and sequence. Later the combination learnt with difficulty becomes by frequent practice automatic. But as these learnt combinations, or even such an elementary combination as walking, becomes automatic, there does not seem to me to be sufficient evidence that their seat of coördination is transferred from the brain to the spinal cord for the reason that if there ensues a lesion of the cortex or of the internal capsule all these so-called automatic movements are lost.

In conclusion, I would like to make some remarks about the *question of representation of movements* of the body of the same side as the cortex stimulated, or, in other words, if the—let us say—left cortex is stimulated what movements, if any, are produced in the left arm and leg. I do not propose to go into the question of the representation in one hemisphere of such bilateral movements as pouting of the lips, mastication, and adduction of the vocal cords. Sir Victor Horsley and myself discussed this question in our paper on the Internal Capsule[50] and the matter has been exhaustively dealt with by Sir Victor Horsley and Professor F. Gotch in their Croonian Lecture before the Royal Society.[51] The question is rather to find out what movements, if any, are produced on the same side as the cortex stimulated and the strength of current which is required to evoke these movements. The subject has been referred to by the various authors. Hitzig[52] in his first memorial remarked that if the currents were feeble their action was localised on the muscles of the opposite side of the body, but if stronger the muscles on the same side of the body were put into action. François-Franck,[53] experimenting on cats and dogs, found that weak currents produced movements of the opposite anterior limb, and if the current be stronger movements of the anterior limb of the same side are produced, but after those of the opposite side. He also found that the movements *persisted* on the two sides in spite of removal of the opposite cerebral cortex, of section of the white matter of the centrum ovale, of division of the corpus callosum, of median section of the bulb, or after section of one half of the cord on the same side as the cortex *stimulated*. He therefore considered that the movements are not caused by impulses conveyed from one hemisphere to the other and he came to the conclusion that the association between the two sides can only take place in the spinal cord by the transverse commissures. According to Unverricht[54] in dogs when the motor cortex of one side—let us say the left—was stimulated epilepsy was produced on the right side and also on the left side. He also obtained convulsions on both sides when unilateral cortical *extirpation* or hemisection of the cord was performed, and this is, he considers, a proof that the convulsions on the same side only arise by centrifugal excitation in the spinal cord itself. But after double-sided cortical extirpation it is not possible to produce clonic contractions.

As I believe that no observations of this nature have been made on monkeys I have made some researches with Sir Victor Horsley who was good enough to perform the operation of electrically stimulating under ether the motor cortex in monkeys. There were done in all *four* experiments and the general results that we obtained were as follows. 1. *On* stimulating the cortical "arm centre" by faradisation with the bipolar method when there was 16–8 centimetres distance between the coils the first movement was in the arm of the opposite side. 2. On increasing the current by diminishing the distance between the coils to about six cubic centimetres movement was obtained in the arm on the same side as that stimulated. 3. The character of the movement on the same side was usually identical with that evoked on the opposite side, but in [illegible] began with extension of the [illegible] me side by adduction of the [illegible] "leg centre" was stimulated the movements on the same side appeared rather sooner than in the case of the arm and in some cases as weak a current with the coils at 12 centimetres apart produced movements in the leg of the same side. 5. Epilepsy was obtained in all the cases in the arm of the opposite side, in three cases it was not obtained on the arm of the same side even to the coil at four centimetres, and in two out of the three cases that it was looked for in the lower limb epilepsy occurred on the same side. The first movement of the epilepsy on the same side was the same as that obtained on the opposite side. 6. On removing the excitable cortex from one hemisphere and stimulating the cortex of the other side, in two of the cases no movements were obtained on the same side as that of the cortex stimulated. In one experiment where movements of interosseal flexion of the fingers, flexion of the wrist, and pronation were obtained the most frequent movement was slow flexion of the fingers under deep narcosis, but under slighter narcosis the movements were the same as on the opposite side. In another experiment the only movement obtained on the same side was slow flexion of the elbow, whether the stimulation was applied to the "arm centre" or to the "leg centre." Also in this animal when the internal capsule was exposed and stimulated very slow flexion of the elbow was obtained on the same side when extension of the wrist and flexion of the fingers were obtained on the side opposite to the stimulated capsule; also very slight extension of the hip and knee were obtained on the same side when marked extension of the toes and flexion of the thigh and knee were obtained on the opposite side. 7. No epilepsy was obtained on the same side as the cortex stimulated when the opposite cortex was removed.

The above experiments are hardly sufficient in number to prove for certain whether the movements occurring on the same side of the body as the cortex stimulated are evoked from the opposite cortex by means of the corpus callosum or from the endings of the pyramidal tract through the commissural fibres of the spinal cord. In two of the cases after removing the left motor cortex there was no movement at all in the right arm on stimulating the right cortex, although there was marked movement in the whole of the left side and even in one case epilepsy. In another case the same movement—slow flexion of the elbow—was produced on the same side irrespectively of the place stimulated and in only one case was there any correspondence of movement between the two sides. On the whole the experiments, as far as they go, are in favour of the theory that in the monkey the movements obtained on the same side as the cortex stimulated are produced from the opposite cortex through the corpus callosum rather than through the commissural fibres of the spinal cord, and that epilepsy is not obtained in the same side of the body as the cortex stimulated if the opposite cortex be removed.

It now only remains to me to thank you, Sir, and those who have attended for their kind attention, and though I taken such a well-known subject as muscular movements I trust that I have brought forward facts which are new as well as true. I cannot conclude without expressing the hope that all students may be taught the muscles taking part in movements on the living person and not on the cadaver.

A BALL will be given on Wednesday, July 1st, at the Empress Rooms, Royal Palace Hotel, Kensington, in aid of the Oxygen Hospital, Fitzroy-square, W.

MEDICAL STUDENTS AND MADAME SARAH BERNHARDT.—On June 22nd Madame Bernhardt appeared at the Adelphi Theatre, Strand, London, W.C., in her rôle of "Marguerite Gautier," the heroine of the eternally attractive story of life and passion by Dumas *fils*. More than a month ago the gallery of the theatre had been reserved, we understand, for this night by Mr. Knox for a number of medi[illegible] after they [illegible] Bern[illegible] Mad[illegible] of hi[illegible] show[illegible] rather a demonstrative manner, but we know that that admiration was sincere.

ABSTRACT OF

The FitzPatrick Lectures

ON

THE HISTORY OF MEDICINE.

Delivered before the Royal College of Physicians of London on June 23rd and 25th, 1903,

BY JOSEPH FRANK PAYNE, M.D. OXON.,

FELLOW AND HARVEIAN LIBRARIAN.

LECTURE I.

Delivered on June 23rd.

MR. PRESIDENT AND GENTLEMEN,—It is right that before entering on the subject of these lectures I should in a few words explain the origin and aim of this new foundation. This lectureship owes its existence to the munificence of a lady, Mrs. FitzPatrick, who desires in this way to honour the memory of her late husband, Dr. FitzPatrick, Member of this College, a physician of great worth, learning, and accomplishments, and at the same time to promote an object which Dr. FitzPatrick himself had much at heart, the advancement of the study of medical history. This pious and generous gift deserves not only what have been gladly rendered, the most cordial thanks of our College, but due recognition from all who are interested in the progress of the two sciences, medicine and history, which it is designed to serve.

In assigning the History of Medicine as the subject of this lectureship the foundress has been guided by the wise advice of our eminent Fellow, Dr. Norman Moore, who was an intimate friend of our deceased Member. While, therefore, the warmest thanks of the College are due, and have been already expressed, to Mrs. FitzPatrick for her munificent gift, we must also recognise the great services of Dr. Norman Moore, to whom, it is understood, are due the conception of this scheme and the plan under which it is to be carried out. It may seem to many, as it seemed to myself, that he would most appropriately have filled the post of the first FitzPatrick lecturer. I would rather that he had been here instead of myself. It was only when I was assured that he, with generous self-abnegation, but decidedly, declined to be appointed that I felt justified in accepting the honourable task which the President and Censors have intrusted to me. I can only say that I will do my best.

It must be confessed, with some shame, that our own country has been, and is, behind most civilised nations in the bulk and value of its contributions to the history of medicine. Germany, France, and Italy have produced on this subject works both profound and brilliant which remain our standard authorities. The smaller countries, such as Holland and Switzerland, have not been behindhand, while our cousins across the Atlantic, the American physicians, are now displaying characteristic energy and zeal in the study of the antiquities of medicine. Compared with the interest shown and the positive results achieved in relation to medical history by the medical profession in all these countries our own countrymen have displayed, I fear, lamentable apathy and but little industry. In one department of the subject only, that is in medical biography, have we any important works to show; for the Roll of our College, as written by our late librarian, Dr. Munk, is certainly unequalled, if not almost unparalleled, in any foreign country. But in general it is true that while England is distinguished above other countries for the zeal with which her political, social, and literary history has been investigated and particularly for the unrivalled series of records and memorials which have been collected for these investigations, the history of science generally, and especially of medicine and of medical institutions, has been conspicuously neglected. I do not forget the excellent work which has been done of late years in connexion with the history of our great Colleges of Physicians and Surgeons and in relation to the history of our Universities. But it is remarkable that while we have done little for the history of medicine in general we have done relatively almost less for the history of medicine in our own country. The history of medicine in Britain, it is not too much to say, remains to be written. If in the standard histories of medicine, chiefly German and partly French, we may sometimes think that the history of British medicine is inadequately represented, this is not the fault of the historians. It is our fault for not having supplied them with adequate materials.

The foundation which is this day inaugurated is the first attempt to have the history of medicine taught or expounded in this country. In considering therefore what department of the vast field of medical history could be advantageously treated within the narrow limits of these two lectures, it seemed best to begin with that part which has been most neglected, the history of medicine in our own country. The range of the inquiry cannot be wide. It is limited no less by the powers and knowledge of the lecturer than by the short time at his disposal. It would be impossible to cover more than a small period of history, and that imperfectly. But if we were to attempt, however inadequately, to lay something like the first stone of the history of English medicine—to make a rough beginning which, it is to be hoped, may be revised and corrected, as well as continued, by other and better equipped investigators—this attempt, humble as it is, may be not without fruit. And the words English medicine, which it seems necessary to employ, imply a still further limitation. There was, no doubt, in all the Celtic countries a traditional popular medicine which had little or nothing to do with the subject of these lectures. In Ireland there was in early times what may be called a learned medicine also. In Wales there seems to have been something like an organised medical profession. But with Celtic medical history the lecturer is totally incompetent to deal, even in the most superficial way. It remains, then, to begin with the earliest record of the English people settled in England, our Anglo-Saxon ancestors, and to try to form for ourselves some idea of what medical science and medical practice meant in those early times. It is there that we find the actual beginning of English medicine.

Now although the history of medicine among the Anglo-Saxons has never been written from a medical point of view, a large amount of material has been collected by the labours of non-medical scholars. During the past generation nearly all, if not the whole, of Anglo-Saxon literature bearing on science and medicine has been collected and translated into modern English by a succession of learned and laborious inquirers. It is to such men as Mr. Thomas Wright, the Rev. Oswald Cockayne, the editors of the Early English Text series, Professor Earle, and others, not forgetting the important contributions made by German philologists, that we owe these important materials for medical history. The following sketch of medicine in Anglo-Saxon times is entirely based upon the labours of these eminent men. And, indeed, to one quite unacquainted, as the lecturer is, with the early English or Anglo-Saxon tongue, it could not be otherwise.

The beginning of Anglo-Saxon civilisation and learning must be dated from the introduction of Christianity into Saxon England by Augustine in A.D. 597. This must also be taken as the beginning of Anglo-Saxon medicine. For though there are some vestiges of earlier popular medical beliefs based on the heathen mythology they are comparatively scanty and unimportant. Whether the Christian missionaries from Rome introduced into England, as modern missionaries often do into heathen countries, some of the medical lore and practice with which they were familiar—that is, the medicine of the Latin world—it is very difficult to say. The earliest hint of anything like medical teaching in England is in connexion with the school at Canterbury founded by Archbishop Theodore in the latter half of the seventh century, about 670. Theodore was a Greek monk from Tarsus who with a learned colleague, the Abbot Adrian, taught both Greek and Latin with such success that many of his pupils, Bede says, knew both the ancient tongues as well as their own. This proficiency in Greek may have had some importance in the study of medicine; but the question is a difficult one. The only evidence that some medical lore was taught at Canterbury rests upon an authentic story told by Bede of one of Theodore's pupils, John of Beverley, afterwards Bishop of York. This divine (who had a reputation for working miracles) being called in to visit a nun, in whom bleeding had been followed by dangerous symptoms, found that she had been bled on an improper day. He severely rebuked those who had ordered the bleeding and quoted some cautions on the subject which had been taught him by his master, Archbishop Theodore. This is an isolated fact, but it shows that learned men among the Anglo-Saxons had some pretentions to medic knowledge and imparted it to their pupils. It is n clear that this was true of the greatest name in t Anglo-Saxon church, the Venerable Bede (died 735) who learning was as remarkable as his piety and zeal. Be wrote beside theological and historical works some scie tific treatises "On the Nature of Things," and "On Times or seasons, dealing chiefly with astronomy and meteorolog There is nothing distinctly medical in his known writing but a manuscript fragment in the British Museum of lat date and doubtful authenticity contains certain rules as the dangerous days for bleeding which are attributed to hi This fragment is so late as to have no authority, but the fa that it refers to a subject which Bede's episcopal pred cessors, Theodore and John of Beverley, thought of gre importance, and one not unconnected with the subject of h known works, gives it some plausibility. In Bede's writin there are references to "leeches" or physicians, showing th there was something like a regular medical profession.

After this the only documents bearing on medicine England belong to the kingdom of the West Saxons a the first date of any importance relating to medicine is th of King Alfred the Great (848–901). This great ruler, w took as much pains to educate his people as to give the laws or to make them successful in war, translated himse and caused to be translated from the Latin into Englis books of history and philosophy; but nothing bearing directl on medicine. By this, however, he set the example which wa afterwards followed in the translation of purely medica works into the vernacular. He kept up relations with Ital and the East even as far as India, by which books of a kinds, probably some medical, were brought into England It appears from an Anglo-Saxon MS. that the patriarc Helias of Jerusalem sent to Alfred from the Holy Lan medical prescriptions relating to such drugs as scammon tragacanth, and others, the produce of Syria, and also th celebrated Greek compound medicine, the "Theriaca Andromachus," or "Triacle," which could not have bee made in England. This shows some interest on Alfred's pa in the progress of medicine.

Soon after the death of Alfred is the date of the mos important Anglo-Saxon medical work which has been pre served. It is a "Leech Book," or Treatise on Medicine i two books. A third book which is appended evidently doe not belong to it. By an inscription at the end we learn tha it was the property of one Bald who ordered one Cild t write it. The presumption is that Bald was a "leech" o physician and that Cild was the writer, but whether th writer was merely the scribe or the author—that is, compiler—is not quite clear. This book is a sort of treatise on diseases, beginning with the head and going down to the feet, as was the custom of the later Greek physicians and almost universally followed in the Middle Ages. Many diseases are mentioned, but the account of their pathology and symptoms is very meagre. The most important passages bearing on these subjects—making, according to the editor, Mr. Cockayne, perhaps one-fourth of the book—are borrowed without acknowledgment from later Greek physicians, especially from Alexander Trallianus and in a few cases from Paulus Ægineta. The question naturally arises whether the Anglo-Saxon compiler read these authors in the Greek or in a Latin version. For various reasons which it would take too long to enumerate it is probable that the latter supposition is correct. Some late Latin writers, such as Marcellus Empiricus and Plinius Valerianus, were also laid under contribution, though none of these authors, Greek or Latin, are named except Pliny. In the book two Anglo-Saxon leeches, Dun and Oxa, are mentioned and reference is made to "the leeches" generally, so that it supplies evidence of the existence of a regular medical profession. The patriarch Helias is the only other person quoted.

The treatment of disease is generally spoken of at greater length than the signs and symptoms. Many prescriptions are borrowed from the Greek physicians but many cannot be thus traced. A conspicuous feature is the great abundance of herbal medicines prescribed. The Anglo-Saxons were acquainted with a large number of native herbs—a knowledge which could not have been acquired from their Greek authorities—and used them empirically along with some exotic drugs. Their pharmaceutical methods were exceedingly simple, herbs being boiled in water or soaked in beer, vinegar, or milk, and sometimes mingled with honey. Ointments were made with butter. The surgery of the "Leech Book" is extremely rude. Wounds were treated with decoctions or poultices of herbs and with honey. For broken bones similar applications were to be used and the limb was to be wrapped in softened elm bark. In one place a splint is spoken of. Amputation is advised only for gangrenous limbs, but no details are given as to the method of performing it. An operation for hare-lip is described but hardly in such a way as to show that the writer had actually performed it. Blood was taken by venesection, cupping, and scarifications. Various kinds of baths are recommended and carefully described. Beside these methods of treatment the "Leech Book" contains a number of charms, incantations, and magical rites, but not so many as some others of the Anglo-Saxon works. The discussion of this subject is deferred.

The "Leech Book" of Bald is found in one manuscript of the British Museum and has been printed in the collection called "Anglo-Saxon Leechdoms" (Vol. II.), edited by the Rev. O Cockayne and published in the "Master of the Rolls Series." The general impression derived from this book, which is the only example of the professional manual of the Anglo-Saxon leech, is that it shows little or no originality but a praiseworthy zeal in trying to obtain the best available knowledge on the subject, new or old, English or foreign. There is nothing in any continental literature of the same period or for some time later at all comparable to it. Indeed, out of Italy there was hardly any scientific literature and none at all in any vernacular language. In this respect the medical literature of the Anglo-Saxons was as much without a rival as their general literature. The misfortune was that this compilation was made when the level of European medicine was at its very lowest. The works of the ancients were mostly inaccessible and nothing else had arisen to take their place. The school of Salerno, the oldest medical school in Europe, had not yet come into prominence.

The next important book which requires notice is the Anglo-Saxon translation of what is known as the Herbarium of Apuleius, a book of medical botany, illustrated with coloured figures. Of this translation no less than four manuscripts have survived, a remarkable number considering the scanty remains of Anglo-Saxon literature which exist and showing that the book enjoyed great popularity. The most remarkable manuscript is one in the British Museum which must originally have been a magnificent book decorated with coloured drawings. It is believed to have been written between 1000 and 1050 A.D. From this and other manuscripts the text has been printed in the Rolls series, edited by Mr. Cockayne with a version in modern English as Vol. I. of "Anglo-Saxon Leechdoms." The original work is in Latin and is attributed to a possibly fictitious writer called Apuleius Platonicus. It is believed to date originally from about the fifth century, but no copy anything like so old as this is known. It was for centuries the most popular botanical book in Europe, being multiplied in numerous Latin manuscripts up to the fifteenth century when it was first printed. Associated with this book in a large number of Latin manuscripts, as in theAnglo-Saxon version, are three other short Latin treatises, one on the plant Vettonica or Betony, attributed, probably falsely, to Antonius Musa, the physician to the Emperor Augustus. There are also a series of descriptions of medical plants, professedly taken from Dioscorides, and a treatise on medicines obtained from animals bearing the name of Sextus Placitus, a Roman physician of the fourth century, all with coloured figures. Who first united these four books in one collection is not known, but taken together they formed a sort of compendium of medical natural history. The essential feature in all of them was the series of illustrations which, as the actual descriptions of the objects are few and meagre, served, or were intended to serve, for the identification of the plants and animals named by the original writers. A large number of Greek and Latin synonyms are given for most of the plants and an enumeration of the diseases for which they were supposed to be useful. All this constitutes, according to our ideas, a very poor book, whether from the botanical or medical point of view. The accounts of medical uses are meagre and often trivial. Even the illustrations, having been handed down by a long succession of copyists, with ever-increasing remoteness from the original objects, are conventional in drawing and often quite unrecognisable in their present form, whatever they may have been in the original. The whole bears no comparison with the genuine work of Dioscorides on "Materia Medica" which is the great treasury of ancient science relating to the natural history and uses of drugs. Nevertheless, the Anglo-Saxons showed their usual intelligence and zeal for knowledge in translating it. It was the best book on the subject they could find, they turned it into their own vernacular tongue and carefully copied the precious illustrations by which they, no doubt, hoped to identify the plants of their own woods and fields and thus to find the key to their virtues and uses as understood by the ancients. This was a distinct step towards the advancement of botany in England, a definite scientific achievement, and as such without a parallel then, or for some time after, in any other European country.

With regard to the coloured figures of plants which occur in the Anglo-Saxon manuscripts, and most conspicuously in that splendid book already spoken of, a few words must be said. It may cause surprise and be thought a fault that the artists did not supply original figures of the plants described. Anglo-Saxon art, which had reached so high a level in decoration and showed considerable skill in drawing the human figure, might be thought to have been equal to this task. But to supply new figures would not have carried out the object which they had in view, which was identification. The artists therefore contented themselves with copying the traditional figures which had already passed through the hands of many generations of copyists. Rude as these figures are, they represent a real survival of old Græco-Roman art and even in their most degraded form preserve some of the features characteristic of classical art in general. The figures are usually nearly symmetrical on both sides and show a sense of balance and proportion which may be fairly regarded as classical. Also they are not so much portraits of individual plants as diagrams constructed from a general knowledge of the object. If [illegible] in the various manuscripts w[illegible] the same, though with occasional varieties, the figures of the same plant in different manuscripts being sometimes quite unlike. The temptation was for a clever artist to treat the figure from a decorative point of view rather than as a mere transcript from nature. Occasionally he allowed his imagination free play and produced figures which are plainly fabulous. These features are clearly seen in some copies now exhibited of the drawings in the manuscripts.

This seems to be the opportunity to say something about the botanical knowledge o[illegible] not be supposed that [illegible] native plants from Latin and Greek sources. A large number of medicinal herbs are named in the various prescriptions of the Leechdoms which are not included in the translated Herbals. We have another source of knowledge in the "glossaries" which give the Anglo-Saxon equivalents for Latin and Greek names of plants. Of these glossaries no less than six written before the middle of the twelfth century, which may be taken as the extreme limit of Anglo-Saxon literature, have been preserved. They show the keen interest which our forefathers took in the knowledge of herbs. From these and other sources Mr. Cockayne has [illegible] the Anglo-Saxon names of wo[illegible] l to between 700 and 800. Or [illegible] of Latin names, synonyms, [illegible] not strictly belong to the period now considered about 500 remain which are either pure English names or Latin and Greek words so altered as to have become vernacular. This is a very large number. The Herbarium of Apuleius with the additions from Dioscorides gives only 185 names and of these some were exotic plants which the Anglo-Saxons could not identify. Evidently, then, a large surplus remains which represents an original English nomenclature of native plants. That the Anglo-Saxons had 5.0 botanical names would not necessarily show that they knew 500 species, for some may have been inaccurate or synonymous, but it is evidence of a [illegible] than they have [illegible] science seems to [illegible] than in mediæval [illegible] French names and [illegible] agree with the hard saying of Professor Earle that "there was a great decadence of botanical knowledge in England between the eleventh and the sixteenth centuries."

In the next lecture some other books of the Anglo-Saxon medical library will be considered and also the charms and magical rites which occur in many of them.

ON THE DIAGNOSIS OF THE CAUSE OF JAUNDICE.[1]

BY SIDNEY PHILLIPS, M.D., F.R.C.P. LOND.,
PHYSICIAN TO ST. MARY'S HOSPITAL AND LECTURER ON MEDICINE IN THE MEDICAL SCHOOL; SENIOR PHYSICIAN TO THE LONDON FEVER HOSPITAL.

OBSTRUCTION in the common bile-duct leads to absorption of bile from the biliary passages and consequent jaundice. This form of jaundice has been termed "obstructive"; and on the assumption that obstruction giving rise to jaundice could only occur in the common duct, all cases of jaundice in which there was no obstruction in the common duct have been termed "non-obstructive." It has, however, been shown that a catarrhal condition of the lining membrane of the small intrahepatic ducts may also produce jaundice which is as much "obstructive" as that produced by obstruction in the common duct. Indeed, most cases of jaundice (if not all) appear to be "obstructive," the obstruction in some being in the small intrahepatic ducts, in others in the common bile-duct, and if the terms "obstructive" and "non-obstructive" are still used in cases of jaundice it must be with the understanding that they refer only to the presence or absence of obstruction in the common bile-duct.

Whatever terms are used the first step in the diagnosis is to determine whether or not there is obstruction in the common bile-duct. Such obstruction is shown by (1) absence of bile from the stools; (2) enlargement of the gall-bladder; and (3) enlargement of the liver.

1. Absence of bile from the stools is the most trustworthy; the other two conditions are confirmatory signs. When the stools are white in cases of jaundice the common bile-duct is obstructed. When they are not white there is no such obstruction. Walker[2] points out that the motions may become colourless from defective pancreatic secretion; in these cases, however, there is no jaundice.

2. Enlargement of the gall-bladder arises from its distension when the common duct is occluded. It may be too slight to be detected at first, but in long-standing cases and where the occlusion is complete it may become enormous and generally can readily be felt through the abdominal wall.

3. Enlargement of the liver arises whenever the exit of secreted bile is prevented. The amount of enlargement varies with the duration of the obstruction and in different individuals. It may appear to be greater than it really is from pushing forwards of the liver by the distended gall-bladder. The enlargement may be so great that doubt may arise as to whether it is not due to primary disease of the liver, but if the surface of the organ is smooth and no nodules can be felt in its substance no degree of enlargement need deter us from regarding it as due to, and confirmatory of, obstruction of the common duct.

The causes of obstruction in the common duct giving rise to jaundice are—1. Morbid conditions involving the duct or its orifice in the duodenum: (*a*) catarrh; (*b*) duodenal ulcer; (*c*) duodenal cancer; and (*d*) stricture of the duct. 2. Foreign bodies in the common duct: biliary calculi, pancreatic calculi, and parasitic structures. 3. Pressure on the duct from without: (*a*) by perihepatitis and resulting adhesions; (*b*) by tumours, aneurysms, or enlarged glands in the portal fissure; and (*c*) by disease of the pancreas.

Jaundice from catarrhal obstruction of the common bile-duct.—Catarrh involving the orifice of the bile-duct in the duodenum prevents bile from flowing into the intestine and jaundice results. When jaundice comes on rapidly with white stools, with slight enlargement and tenderness of the gall-bladder and liver, but without pain or ascites, the probability is that the jaundice is due to catarrh, especially if there have been precedent symptoms of gastro-duodenal indigestion (nausea, flatulence, &c.), with or without evidences of rheumatism, gout, or secondary syphilis. The diagnosis of catarrhal jaundice is not based on any special distinctive symptom but rather on the known frequency of its occurrence, together with absence of evidence of any other condition which could produce jaundice. Catarrhal jaundice rarely lasts more than five or six weeks, but during this time the gall-bladder may become considerably distended and the patient may become very deeply jaundiced and emaciated. If the jaundice does not commence to lessen after the lapse of five or six weeks and bile to reappear in the stools, the diagnosis of simple catarrh must be abandoned, the probability being that some more serious condition, such as disease of the pancreas, is present.

Jaundice from duodenal ulcer can only arise when the ulcer involves the opening of the common duct in the duodenum; it is therefore rare. Jaundice with white stools and no ascites, coming on after the patient has suffered for some time from epigastric pain and tenderness, with hæmatemesis or melæna, is ascribable to duodenal ulcer. (The same symptoms may result from cancer of the pancreas, but then the jaundice usually precedes any hæmorrhages and possibly the tumour of the pancreas can be felt.)

Jaundice from duodenal cancer.—If in addition to the symptoms of duodenal ulcer just enumerated, a tumour can be felt in the duodenal region, or if the lymphatic glands in the abdomen, neck, or elsewhere are enlarged, the jaundice is probably due to duodenal cancer. (Cancer of the head of the pancreas is even more difficult to exclude here than in the case of simple duodenal ulcer, but in cancer of the pancreas the jaundice usually precedes the melæna and there may be other evidences of pancreatic cancer such as will be described later.)

Stricture of the common bile-duct.—Jaundice coming on at birth with absence of bile from the stools is ascribable to congenital stricture of the duct, and is soon fatal. Acquired stricture of the duct is rare and seems most commonly to result from previous passage of gall-stones, but cases without any evidence of previous gall-stones have been recorded by George Johnson, T. Holmes, Moxon, and myself.[3] Jaundice can only be attributed to stricture of the common duct when all other possible causes can be excluded.

Jaundice from calculi or other foreign bodies in the common bile-duct.—When jaundice, with white stools and enlargement and tenderness of the gall-bladder and liver, comes on a few hours after a paroxysm of acute abdominal colic, with retching or vomiting, and may be pyrexia, such jaundice is usually due to a foreign body in the common bile-duct, and in the absence of evidence of hydatids of the liver such foreign body is presumably a biliary calculus (A pancreatic calculus impacted at the orifice of the common bile-duct may produce almost identical symptoms though probably with less severe pain, as in the case by A. P. Gould, published in the Transactions of the Clinical Society of London for 1889.) Jaundice must no be ascribed to impacted gall-stone unless there has bee an attack of colic *at some time*; for though a calculus ma become impacted in the duct without an *immediately* preceding attack of pain, yet it is excessively rare for a stone t become so impacted unless calculi have entered the biliar passages and produced colic at some previous date—it ma be long before. Jaundice must not be too readily attribute to gall-stones if the evidences of their existence occurred a some long previous date, for such jaundice may be due t cancer of the liver or pancreas, which are not infrequentl preceded by calculi in the biliary ducts.

Jaundice from compression of the common duct by perihepatitis with adhesions.—Perihepatitis seldom occurs as disease alone, but is met with in association with hepatiti (especially syphilitic hepatitis), with growths in the liver c portal fissure, with gall-stones in the biliary passages, or wit gastric or duodenal ulcer. As the vena portæ as well a the duct may be compressed by the perihepatic bands, ascite is often produced as well as jaundice. When jaundic occurs without bile in the stools, but with ascites, paroxysma attacks of local pain and pyrexia, together with evidences c some of the conditions above enumerated with which perihepatitis is usually associated, we are justified in attributin it to perihepatitis. When similar symptoms occur, bu without ascites, the diagnosis is more difficult, the mai difficulty being to decide whether the symptoms are due t gall-stones or to perihepatitis, for both give attacks c pyrexia, local pain, and jaundice with colourless stool The more severe the attacks of pain and the more intense th jaundice, the greater the probability of calculi; but ver often perihepatitis and gall-stones coexist and many of th symptoms met with in cases of gall-stones are due t associated perihepatitis.

[2] Transactions of the Royal Medical and Chirurgical Society, vol. lxii., p. 257.

[3] Transactions of the Clinical Society of London, 1888.

The following cases exemplify the resemblance between the symptoms produced by perihepatitis and those producible by gall-stones.

CASE 1.—A married woman was admitted into St. Mary's Hospital in 1878 for enlargement of the liver; after that she was well till 1889 when she came to me as an out-patient with pain, jaundice, and colourless stools; she improved temporarily but came again into the hospital in August, 1890, with jaundice, colourless stools, and epigastric pain and tenderness. No enlargement of the liver could be detected. In October the abdomen was opened by Mr. A. J. Pepper; no gall-stones were found but the gall-bladder was shrunken and there were numerous tough perihepatic inflammatory bands. These were divided as far as was deemed prudent and she was greatly relieved. I saw her again in May, 1894, with large syphilitic nodes on the legs and occasional smarting pains in the liver region but no jaundice. Syphilis here seemed to have caused perihepatitis and jaundice simulating gall-stones, but there was never pain severe enough to be called "colic."

CASE 2.—The patient was a married woman, aged 46 years, who had for five years suffered from attacks of biliary colic and in February, 1900, she had severe rigors and high temperature, with deep jaundice, colourless stools, and pain in, and enlargement of, the gall bladder. I saw her in June,
1900, with Mr. E. Moon
bladder was made by M
and puckered, adherent to the stomach by inflammatory bands, and two calculi in the common bile-duct. Some of the adhesions were divided but there was a widespread matting of tissues around the duct, which it was not thought wise to interfere with, and the calculi were too firmly impacted to remove. The wound healed and the fever and pain soon subsided. The patient was greatly relieved by the division of the adhesions and eventually lost her jaundice.

Jaundice from compression of the bile-duct by tumours in the portal fissure.—Any tumour pressing on the common bile-duct sufficiently to occlude it will press also upon the adjacent vena portæ; hence in such cases there is always ascites as well as jaundice. If a tumour can be detected in the region of the portal fissure and there is ascites as well as jaundice, with colourless stools, there need be no hesitation in ascribing the jaundice to the presence of the tumour. When the same symptoms occur without any tumour being detectable, but nodules of carcinoma can be felt in the liver, we may infer that the jaundice results from pressure on the bile duct by glands in the portal fissure, secondarily affected. The physician should never attribute jaundice with colourless stools, but without ascites, to cancer of the liver. Cancer of the liver does not itself press upon the bile-duct (except in very rare instances) and any obstruction of the bile-duct in cases of cancer of the liver is produced by pressure of secondarily affected glands in the portal fissure, which are certain to produce ascites if they produce jaundice. Even if nodules of carcinoma can be felt in the liver jaundice with white stools is not to be ascribed to that disease unless there be also ascites, but is probably the result of cancer of some other organ such as the pancreas to which the nodules in the liver are secondary.

Jaundice from disease of the pancreas is more common than might be inferred from the little stress until recently laid upon it. From the anatomical position of the gland tumours or enlargements of the head of the pancreas, unlike other tumours or enlarged glands in the portal fissure, can press upon and occlude the common bile-duct without compressing the vena portæ. Hence disease of the pancreas is capable of producing jaundice with colourless stools but without ascites—symptoms closely resembling those producible by gall-stones but distinguishable from them by the absence of severe colic. When jaundice comes on, either slowly or quickly, with white stools, without pain, or if with pain without the acute paroxysm of biliary colic or of perihepatitis and without the indications already described of duodenal ulcer or cancer, the jaundice is due either to disease of the pancreas or to catarrh of the common duct. If a tumour can be felt in the position of the head of the pancreas catarrh is excluded. Pain, too, would also exclude mere catarrh. If there is no tumour and no pain the diagnosis between catarrh and pancreatic disease is impossible for the time, but if the jaundice persists for over six weeks the presumption becomes great that it is not due to simple catarrh and is in all probability a result of disease of the pancreas. Confirmatory evidences of pancreatic disease may be present.

The enlargement of the gall-bladder which results from pancreatic as from all other forms of obstruction of the common duct is apt to be more marked in pancreatic growths than from other causes, such as gall-stones, for the obstruction from pancreatic disease is often more absolute than from gall-stones and, again, the latter often set up inflammatory adhesions about the gall-bladder which limit its distension. Bard and Pic[4] deny that enlargement of the liver occurs in cases of pancreatic obstruction of the duct, but Chopin and Molle[5] have shown that the liver may enlarge in this as in all other forms of obstruction of the common duct, and the post-mortem examinations in some of my own cases have shown that the liver may become of enormous size. In late stages there are often secondary nodules of cancer in the liver. Ascites is more often absent than present but may arise in the late stages of pancreatic disease. A tumour may be sometimes felt but a small growth in the head of the pancreas quite incapable of being felt through the abdominal wall may produce jaundice. In three of 12 cases of pancreatic growth no tumour could be felt. Fat in the stools sometimes occurs. Œdema of the feet without ascites may result from pressure on the inferior vena cava. Pain is usually, but not always, felt; it was absent in three of 12 cases. Melæna is not infrequent—it occurred in four of 12 cases; in one the disease had ulcerated into the duodenum. Secondary growths may occur in the skin or in the mediastinum (two cases). Glycosuria appears to be most common in non-malignant cases but it may occur in carcinoma of the pancreas, as in a case recorded by Shaw and Perry.[6] It is said that pancreatic obstruction prevents carboluria when salol is administered by the mouth. In one case now in Victoria Ward with presumably cancer of the pancreas, salol produced carboluria immediately. (Subsequently the necropsy of this patient showed obstruction of the bile-duct by cancer of the pancreas.) This and other cases of proved pancreatic obstruction have shown that the administration of salol is worthless as a test of pancreatic obstruction.

The statement has been made that cancer of the pancreas, unlike cancer of the liver, does not appear to be predisposed to by calculi in the biliary passages, but in two of my 12 cases pancreatic cancer as well as biliary calculi were found post mortem and in a case recorded by Shaw and Perry there was evidence of the same association. A previous history of gall-stones therefore in no way militates against the diagnosis of pancreatic cancer as a cause of jaundice. The nature of the disease of the pancreas suspected to be the cause of jaundice must be adjudged on the grounds which guide us generally, any solid tumour detectable in the position of the pancreas or any enlargement of cervical lymphatic glands pointing to malignancy.

CASE 3. *Carcinoma of the head of the pancreas producing jaundice and œdema of the feet.*—A man, aged 51 years, suffered from jaundice in August, 1899, and was sent to me at St. Mary's Hospital by the late Mr. J. C. Barr on Jan. 30th, 1900. He had jaundice. The stools were white: the liver was large and smooth, reaching to the level of the umbilicus, and there was a *tense pear-like gall-bladder* No other tumour could be felt. There were no pain and no ascites but there was *swelling of the feet and ankles.* An operation by Mr. Pepper, on the possibility of the diagnosis being wrong, showed an irremove-
organ. The wound healed

reas with calculi in the gall-bladder.—A widow, aged [illegible] years, came into St. Mary's Hospital on March 7th, 1902, complaining of pain in the abdomen, the hip, and the right shoulder. There were occasional vomiting, jaundice with colourless stools, no ascites, a tumour palpable in the epigastrium, and slight pyrexia. Laparotomy was performed by Mr. Pepper and showed carcinoma of the head of the pancreas and secondary nodules in the liver She had been a patient in the hospital eight years before for jaundice and suspected gall-stones At the necropsy on April 6th numerous small calculi in the gall-bladder and cancer of the pancreas with secondary nodules in the liver were found to be present.

CASE 5 *Cancer of the pancreas and calculi in the gall-bladder.*—A female, aged 54 years, came under my care at St. Mary's Hospital on March 22nd, 1901, with severe epigastric pain and a much distended gall-bladder but no jaundice; she wasted rapidly, but soon went out of hospital, only to return in June, 1901, with deep jaundice, colourless stools, a tender tumour in the epigastrium, and enlargement of the cervical lymphatic glands. She died on July 22nd and there were found carcinoma of the head of the pancreas and numerous calculi in the gall-bladder. Here enlargement of the gall-bladder resulted from the calculi and later jaundice from the cancer of the pancreas.

CASE 6. *Carcinoma of the pancreas with jaundice and melæna.*—A married woman, aged 46 years, was quite well till one morning in the early part of May, 1902, she found that she was jaundiced. About the middle of June attacks of vomiting commenced. She came under my care at St. Mary's Hospital on August 11th with deep jaundice and colourless stools. No tumour could be felt but the liver was very hard and smooth and its sharply defined lower edge could be felt below the level of the umbilicus. She had no pain except at the tip of the right shoulder; there had never been any pain in the lower region. No ascites existed. Salol given by the mouth produced carboluria in a few hours with great aggravation of the toxic symptoms from which she was then suffering; it was at once discontinued. She slowly got worse and twice passed blood by the rectum towards the end of the illness. The enlargement of the liver increased and the gall-bladder could be sometimes felt. She died comatose on Dec. 8th. The necropsy showed a hard mass of cancer in the head of the pancreas which had commenced to ulcerate into the duodenum. The liver was very large and hard and gorged with bile and as the latter ran out the liver rapidly lessened in size. The gall bladder was much distended but its tip only just came beyond the liver edge.

Jaundice without obstruction in the common bile-duct occurs in many conditions and for reasons not well understood. That it is due to a failure of the liver to secrete bile is disproved by the fact that when the liver fails to secrete bile no bile is secreted and therefore no jaundice results. The theory that the jaundice is a result of excessive absorption of bile from the intestines has also been disproved. In many cases the jaundice appears to be due to absorption from the small intrahepatic ducts of bile which has become more or less stagnant owing to a catarrhal condition of the epithelium lining these ducts set up by some poison in the blood. No explanation, however, quite satisfactorily accounts for the appearance of jaundice in all the conditions in which it occurs. They may be enumerated as follows: (1) poisons circulating in the blood, such as phosphorus, toluylendiamin, &c.; (2) toxins resulting from certain diseases—yellow fever, the exanthemata, pyæmia, &c.; (3) congestion of the liver; (4) hepatitis; (5) acute atrophy of the liver; and (6) conditions of the nervous system.

Jaundice from poisons.—Though we cannot satisfactorily account for the mode of causation we may set down jaundice as due to phosphorus poisoning if there is evidence that this substance has been taken.

Jaundice resulting from yellow fever, &c.—When jaundice occurs in the course of any of the diseases already enumerated we may similarly attribute the jaundice to the toxins of the disease.

Jaundice from congestion of the liver.—When there is jaundice with bile in the stools and the liver becomes enlarged and tender, with perhaps nausea or vomiting, we may infer that the jaundice is due to congestion of the liver, especially if it occurs in a tropical district.

Jaundice from hepatitis.—When the liver is much enlarged and smooth or "hobnailed" on its surface, or is much contracted, and especially if there are evidences of alcoholism, such as morning retching, with or without signs of portal obstruction, any jaundice which occurs with presence of bile in the stools may be set down as due to the cirrhosis and is, indeed, a confirmatory evidence of it. The form of cirrhosis in which jaundice is most common is the unilobular form with a large smooth liver and no ascites, but it may occur in the large liver with ascites, or in cases where the liver is contracted with or without ascites. Probably in most of such cases the jaundice is due to a catarrhal state of the small ducts.

CASE 7.—A man, aged 50 years, who denied alcoholic habits but who was afterwards ascertained to have drunk a bottle of whisky a day, had been in Africa a good deal but had no signs of malaria. In November, 1900, he began to feel ill and in February, 1901, became jaundiced with pain in the umbilical region. He was admitted under my care at St. Mary's Hospital on April 15th deeply jaundiced; there was bile in the stools and urine; there was no ascites. The liver was very hard, quite smooth, and reached down to the level of the umbilicus. He had lost two stones in weight in six months, but cancer of the liver was excluded by the smoothness of the surface of the liver and hepatitis was diagnosed. He remained about the same till May 7th, when he became drowsy and soon afterwards had a purpuric eruption over the body and legs. He went out of hospital on May 30th but I saw him again with his medical man at home dying comatose from jaundice with copious ascites.

NOTE ON THE PERSISTENCE OF THE GRUBER-WIDAL REACTION IN CONVALESCENCE FROM TYPHOID FEVER.

BY H. S. D. BROWNE, B.A. CANTAB., L.R.C.P. LOND., M.R.C.S. ENG.,
CLINICAL ASSISTANT IN THE THROAT DEPARTMENT, ST. THOMAS'S HOSPITAL;
AND
K. E. CROMPTON, B.A., M.B. CANTAB.,
LATE HOUSE PHYSICIAN TO ST. THOMAS'S HOSPITAL

CURSCHMANN, in Nothnagel's "Encyclopædia of Practical Medicine,"[1] makes the following statement: "Among the sources of error in serum diagnosis the important observation should, in conclusion, be considered that the agglutinating action of the serum may persist for months, and even years, after recovery from an attack of typhoid fever" (Lichtheim, C. Fränkel, Stern). If this observation holds good for the majority of cases the presence of a serum reaction in an old typhoid fever patient with a fresh attack of fever of doubtful nature might easily lead to an error in diagnosis. But the consideration of a large number of cases investigated by other observers leads one to the conclusion that the persistence of the serum reaction after the first few months of convalescence is the exception rather than the rule.

Widal[2] examined 40 cases, of which 11 gave a positive reaction, one giving a reaction eight and a half years afterwards with a dilution of 1 in 1800. Fison[3] examined 21 cases from three months to eight years after attacks, of which 18 gave positive reactions. Renard[4] examined 104 cases, 35 of which gave positive reactions, five of these being 20 years after the attack. Elsberg[5] investigated 36 cases and found the reaction present in eight cases one month after convalescence. He also found that the reaction had disappeared in one case in the fifth week of convalescence and in two cases in the third week of convalescence. It is interesting to note that the above observers used very different dilutions in their experiments. Thus Fison used 1 in 2 and 1 in 9 with a 30-minute time limit. Renard used 1 in 10 except in one case, when he obtained a reaction in 1 in 40. Cabot makes no mention of the dilution used by Widal.

We have examined the serum of all the cases of typhoid fever treated at St. Thomas's Hospital from 1899–1901 which we have been able to reach by letter. In this series of cases the typhoid bacilli used were the descendants of a single colony obtained from the case of multiple typhoid abscesses operated on by Dr. H. C. Jonas in St. Thomas's Home and reported by him in conjunction with Dr. C. G. Seligmann.[6] From 18 to 24 hour old agar cultures were used by us. These were emulsified with tap water and the emulsion was passed through filter paper in every case to avoid false clumps. Each emulsion was carefully examined before use and those possessing the highest degree of motility were selected. A control of the emulsion used was examined in every case. A dilution of 1 in 10 was first used in all cases. When any indication of reaction occurred 1 in 20 and 1 in 50 dilutions were proceeded with; the time limit was half an hour in all cases. The sera were thus put to exactly the same test as that to which they had been subjected in the original attack. No cases were selected which had not previously given the

TABLE SHOWING THE SERUM REACTIONS IN 68 CASES AT VARIOUS PERIODS AFTER RECOVERY FROM TYPHOID FEVER.

Months after the attack.	Total number of cases.	Positive reaction.	Negative reaction.	Details of the negative cases showing indication of reaction.
1–6	2	1	1	One case with a dilution of 1 in 10 gave loose clumps with very little loss of motility.
7–12	11	1	10	One case with a dilution of 1 in 10 gave well-marked clumps with incomplete loss of motility; a 1 in 20 dilution gave a few clumps with no loss of motility. One case with a dilution of 1 in 10 gave a complete reaction; a 1 in 20 dilution gave a few clumps with no loss of motility.
13–18	15	—	15	Two cases with a dilution of 1 in 10 gave clumping in five minutes [illegible] of 1 in 20 there were loose clumps and slight loss of motility. [illegible] clumps with very slight loss of motility; a dilution [illegible] absolutely negative. One case gave a complete rea[illegible] loose clumps with slight loss of motility, and on[illegible] dilution of 1 in 10 gave well marked clumps with [illegible] negative.
19–24	17	2 (doubtful)	15	[illegible]
25–30	7	—	7	One case with a dilution of 1 in 10 gave a complete reaction; one of 1 in 20 clumped in 15 minutes; the loss of motility was incomplete in 30 minutes; and one of 1 in 50 was absolutely negative. One case with a dilution of 1 in 10 gave a complete positive reaction and one of 1 in 20 was absolutely negative.
31–36	9	—	9	One case with a dilution of 1 in 10 gave loose clumps with little loss of motility; one of 1 in 20 gave a like result; with one of 1 in 50 there were a few loose clumps and no loss of motility.
37–42	4	1	3	—
43–48	3	—	3	—

standard positive Widal reaction at the time of attack—i.e., absolute clumping and loss of motility in 30 minutes with a dilution of 1 in 50. None of the patients had suffered from any acute fever in the interim. In the cases which are quoted in the accompanying table as giving an indication of reaction a reaction more or less marked took place with the low dilution, but this became weaker with 1 in 20 and was absent with 1 in 50.

Two of the cases were doubtfully positive 1. The patient was a male, aged 44 years. The test was made 22 months after the attack. No illness had occurred in the interim. During the attack the serum gave a positive reaction with a dilution of 1 in 100. A dilution of 1 in 10 gave tight clumps with absolute loss of motility in 10 minutes; one of 1 in 20 gave tight clumps with incomplete loss of motility in 30 minutes; and one of 1 in 50 gave a few loose clumps with slight loss of motility in 30 minutes. 2 The patient was a male, aged 25 years. The test was made 23 months after the attack. Dilutions of 1 in 10 and 1 in 20 respectively gave tight clumps with absolute loss of motility in 25 minutes; with a dilution of 1 in 50 the clumps contained motile bacilli. The loss of motility was incomplete.

Three of the cases gave a positive reaction. 1. The patient was a male, aged five years. The test was made two months after the attack. With a dilution of 1 in 50 there were instantaneous clumping and loss of motility. 2. The patient was a male, aged 33 years. The test was carried out 12 months after the attack. A dilution of 1 in 50 gave instantaneous clumping and loss of motility. 3. The patient was a male, aged eight years. The test was made 38 months after the attack. The reaction was complete with dilutions of 1 in 20 and 1 in 50 respectively. The patient in No. 2 was operated on for gall-stones five months after his attack of typhoid fever; at the operation pus and some small gall-stones were found. The pus gave cultures of the colon bacillus, but serum gave a positive reaction with the bacillus typhosus. This case is of interest, being analogous to cases quoted by J. B. Miller,[7] when in an operation seven years after the attack typhoid bacilli were found in the gall-bladder and serum gave a positive reaction, and by Elsberg,[8] when in cases of osteomyelitis following typhoid fever five months and 16 months respectively after an attack serum gave a positive reaction. In No. 3 nothing could be found to explain the persistence of so strong a reaction after a lapse of more than three years.

Conclusions.—From the accompanying table of 68 cases it is seen that only three cases gave a positive reaction, one of which was only two months after the attack. This is a much smaller proportion of positive reactions than is given by Renard (35 out of 104), Fison (18 out of 21), Elsberg (eight out of 36), and Widal (11 out of 40). The difference is due partly to the inclusion by them of cases in which only a few weeks had elapsed since the original attack and partly to the low dilutions used by them—e g., Renard 1 in 10 and Fison 1 in 2 and 1 in 9. If we had considered a positive reaction with 1 in 10 sufficient our list would have shown eight more positive reactions, bringing our proportion up to 11 out of 68. While, however, we have no doubt that the reaction with the low dilution shows that the blood in some cases retains for a long time the specific agglutinating action on the bacillus typhosus, yet we wish to insist that this need lead to no error of diagnosis provided that sufficiently high dilutions—i.e., 1 in 20 or 1 in 50—are proceeded with in cases in which there is any doubt.

Elsberg states that he found no relation between the severity of the attack and the duration of the reaction. Our observations are in accordance with this. Many of our negative results were obtained from cases which had had severe attacks, often with relapses, while the patient in whom the only positive result, which cannot be explained on other grounds, had been obtained suffered from a mild attack [illegible] ...se falls in line with [illegible] and supports the [illegible] ...tion is due to the continued pr[illegible] ...phosus in the gall-bladder and elsewhere long after the original attack of fever. But the case described by Dr. Jonas and Dr. Seligmann,[9] [illegible] abscesses two years after [illegible] a partial reaction with [illegible] of this theory. (See also the case of [illegible] quoted by Dr. Jonas and Dr. Seligmann.)

DONATIONS AND BEQUESTS.—The Belfast Society for the Relief of Destitute Sick, the Belfast Nurses' Home and Training School, the Belfast Society for Providing Nurses for the Sick Poor, and the Greencastle District Nursing Association receive £1000 each under the will of the late Mr. James Gray of Antrim.—Miss M. A. Kirby of Bristol has bequeathed £2000 to the Bristol Royal Infirmary and a like sum to the Bristol General Hospital.

ON THE USE OF THE ROENTGEN RAYS IN THE DIAGNOSIS OF PULMONARY DISEASE.[1]

BY J. F. HALLS DALLY, M.A., M.B., B.C. CANTAB., M.R.C.S. ENG., L R.C.P. LOND.,
ASSISTANT RESIDENT MEDICAL OFFICER, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.

IN addition to the established methods of medical investigation of diseases of the chest comprised under the headings of inspection, palpation, percussion, auscultation, and mensuration we now have at our disposal the Roentgen rays, a newer yet not less potent factor in diagnosis. These rays, accidentally discovered by Professor Wilhelm Konrad Roentgen of Würzburg towards the close of the year 1895, although their nature and scope are as yet imperfectly understood, play nevertheless a most important part in diagnosis, prognosis, and treatment. For some time past the surgeon has found them of special value when he is called upon to reply to the many difficult questions which arise in the practice of his profession concerning injuries and diseases of the osseous system. It is only quite recently, however, that their uses to the physician have been clearly recognised and at the present time we seem to be standing on the threshold of discoveries which will prove to be of wide and far-reaching importance in the daily detection of deep-seated and obscure affections.

In a new science a new terminology is desirable in order that conceptions of new facts may find their adequate expression, and in the course of this paper a few terms will be found for the first time, amongst them being the adjective "transradiant" and its corresponding noun "transradiancy," which have been used in order to express more clearly the idea of permeability of the chest to the Roentgen rays than does either of the terms, "translucency" or "transparency," hitherto in vogue. Although, according to the recent researches of M. Blondlot,[2] the Roentgen rays appear susceptible of polarisation and may eventually be found to conform to the laws of light, yet the use of the term "translucent" implies an assertion which has not at present been proved. No such objection can be brought against "transradiant." Under their proper headings hereafter the "cardio-phrenic space" and "pleuro-pericardial lines" will be referred to.

My object is not to dissociate the Roentgen rays from the other modes of physical clinical research—although at times, as I shall show later, an accurate diagnosis may be based on the evidence which the rays afford, taken by itself alone—but to bring them into line with the older methods, an outline comparison with which will be found in the accompanying tables :—

METHOD.

$$\left.\begin{array}{l}\text{Radioscopy} \;\ldots\;\ldots\;\ldots\;\ldots\\ \text{Radiography} \;\ldots\;\ldots\;\ldots\;\ldots\\ \text{Stereoscopic}\left\{\begin{array}{l}\text{Radioscopy}\\ \text{Radiography}\end{array}\right.\\ \text{Localisation} \;\ldots\;\ldots\;\ldots\;\ldots\end{array}\right\} = \left\{\begin{array}{l}\text{Inspection.}\\ \text{Palpation.}\\ \text{Percussion.}\\ \text{Auscultation.}\\ \text{Mensuration.}\end{array}\right.$$

RESULT.

Roentgen rays.		*Percussion.*
Brightness	=	Hyper-resonance.
Transradiancy	=	Normal resonance.
Faint shadow	=	Impaired resonance.
Dense shadow	=	Dulness.
Opacity	=	Absolute dulness (tanquam femoris).

Thus it is clear that the so-called physical signs are really the results obtained by the use of a physical method.

Much of the practical work in connexion with this subject was done during my clinical assistantship at the City of London Hospital for Diseases of the Chest, Victoria Park, and I am greatly indebted to Dr. Hugh Walsham for his kindness in placing at my disposal so much excellent clinical material and apparatus and for the many helpful suggestions which he has made from time to time. To Dr. H. Lewis Jones also my thanks are due for the facilities granted to me for working in the electrical department at St. Bartholomew's Hospital.

RADIOGRAPHY AND RADIOSCOPY OF THE THORAX.

The apparatus which is essential comprises: (*a*) a means of generating the electrical current—usually an induction coil or static machine; (*b*) a vacuum tube and holder; (*c*) a sensitised photographic plate; and (*d*) a fluorescent screen.

Having first tested the apparatus to make sure that it is working properly the patient should then be brought in and placed in the required position—usually seated or recumbent; the plate is held securely against the thorax so that it cannot move and the current is started. The time of exposure is important and depends on many factors. With the tube at a distance of about two or three feet from the patient an exposure of from one to three minutes is usually sufficient. The penetration of the tube should not be too great, otherwise structures, which should appear dense, become transradiant. In like manner over-exposure of the photographic plate causes obliteration of shadows. The plate should always be placed with the film side next to the skin, because this insures sharper definition and also prevents some of the rays from being absorbed by the glass.

In order to know in a radiograph which is the right side and which is the left the relative position of the focus-tube to the patient and the film side of the plate must always be stated. We know that for any shadow to be cast at all the patient must be between the tube and the plate, and a comparison may be instituted between the skiagraphic effect thus obtained and that produced in the familiar "shadow show" by the interposition of objects which arrest the rays in their passage from a magic-lantern to the white screen. As Mr. J. Mackenzie Davidson[3] has well remarked, "These pictures consist of shadows projected by the rays from a fixed point; a skiagram must not be regarded as if it were a map." The proper interpretation of x-ray pictures can be brought about only by careful and repeated observations, but, thanks to stereoscopy, we can now bring to our aid the third dimension in space, so that a better estimate can be formed concerning the relative proportions of parts. The observations which follow were all made with the aid of an induction coil capable of giving a 14-inch spark at high pressure between the terminals of the secondary coil, which is composed of some 15 miles of wire wound in 70 sections. It is worked by two 4-cell accumulators, charged by continuous current from the main, of 21 ampère-hours' capacity and a total electromotive force of 16 volts. The tubes used were those made by C. H. F. Müller of Hamburg, of moderate "hardness" or penetrative power, the platinum anode being placed always exactly opposite the centre of the part to be photographed and the distance of the tube between one and two feet from the thoracic parietes.

The method of radioscoping the thorax is precisely the same as for radiography except that for the photographic plate we substitute the fluorescent screen and bring the tube nearer to the chest. The tube must not be placed in too close proximity, otherwise, owing to divergence of the rays, just as in the shadow show referred to above, the shadow of structures near to the tube will appear larger and more indefinite than that of structures more remote.[4] Examination with the tube posteriorly as well as anteriorly will help in great measure to correct erroneous impressions based on an examination from one aspect alone. Another equally important point, which cannot be insisted on too frequently, is that the anode should directly face the centre of the part to be observed with its surface parallel to the greatest transverse diameter of the chest.

RELATIVE USEFULNESS OF THE FLUORESCENT SCREEN AND THE RADIOGRAPH.

For some time past the question has been discussed as to the superiority or otherwise of radioscopy to radiography. The truth of the matter seems to be that both methods are indispensable and that the choice of one or the other is to be regulated according to circumstances. Where, as in hospital, one has to examine a number of patients it is manifest that in each individual case radiography is out of the question, for in a large proportion of these a diagnosis may be furnished at once on the results of radioscopy combined with auscultation and percussion. I think that in every case examined by means of the x rays a screen examination should be instituted, whether a photograph be subsequently taken or not, and that in a case presenting any difficulty, where it is of importance, from the point of view of after-treatment, to arrive at a correct diagnosis, one or more radiographs taken from different points of view should always supplement the fluoroscopic investigation. In private cases both methods should be used, for the action of the rays is cumulative and minute details which cannot be detected by the screen show clearly in the developed plate. Moreover, radiographs can be taken at successive dates and the progress of the disease thus noted. The fluoroscopic evidence is fleeting, although by making graphic records at the time of examination we may obtain some of the advantages of the radiographic method. In short, radioscopy records dynamic and radiography static conditions.

THE NORMAL THORAX.

The radiograph of a normal thorax, whether examined from the front or the back, presents a well defined median opacity bounded laterally by parallel vertical margins on each side of which appears a transradiant area crossed by curved and arching shadows. This median vertical band of opacity corresponds with a resistance to permeability due to the vertebral column, the sternum, and the mediastinum with its contents; from the upper part of this band stretch two narrow shadows upwards and outwards—these correspond to the clavicles. Laterally the mediastinal shadow does not extend far beyond the limits of the sternal shadow. If the picture be taken with the tube placed posteriorly a shadow, somewhat triangular in outline, will be seen extending much more to the left than to the right of the thorax. This does not obscure the outline of the curved shadows referred to above, which represent the ribs, and corresponds to the heart and pericardium. By means of the fluoroscope a pulsation synchronous with each heart-beat may be observed

Alongside the mediastinal opacity and following the outline of the cardiac shadow are seen in many radiographs faint and ill-defined lines or streaks the nature of which is still uncertain (*vide* Fig. 1, *b*). It was originally thought that these lines represented the lower bronchi and bronchioles Later these streaks were attributed to mediastinal glands. Another opinion, first put forward by Dr. Walsham,[5] is that they are "due to the visceral pleura covering the inner surface of the lungs, as seen edgeways, and to the pericardium."

That these lines are not caused by the bronchi is, I think, clear for two reasons. It will be seen, in the first place, that the position of the lines does not correspond with the divisions of the bronchi. Even granting that these lines were so caused their position is such that they could be caused only by the lower ones No shadows are visible representing the bronchi, or the smaller tubes into which they divide, for the upper lobes, and it is difficult to see why these should not cast a shadow as well as the lower ones. Hence this suggestion appears untenable. In the second place, in all post-mortem radiographs of lungs which I have seen—a good example being reproduced in a paper by Dr. F. Gardiner[6] and another in Dr. Francis Williams's[7] book—the larger primary bronchi show, *not* as dark streaks or shadows, but as light areas, owing probably to their contained air, their density in the former specimen being equivalent to that of cavities present in the same lung and a little brighter than a patch of emphysema at the apex. It is improbable that the streaks are produced by mediastinal glands, for these are more mesial and produce, not lines, but patchy and irregular shadows.

With regard to the third view, I agree with Dr. Walsham[8] that a portion of the lines is due to the pericardium, but that the "visceral pleura" takes any share in their causation seems impossible from a consideration of the post-mortem skiagrams adduced in support of his opinion, for in the third and fourth radiographs taken with the lungs—and with them the visceral pleura—removed these lines still remain. That they are not due to the pericardium alone is clear, since in favourable cases they may be seen extending upwards as high as the sternal ends of the clavicles. To these streaks Dr. Walsham has applied the terms "cardiac lines" and "mediastinal lines" respectively, but since in all probability they belong to the junction of the parietal pleura with the pericardium and are manifestations of these, being radiographically continuous, I venture to suggest (under correction) the term "pleuro-pericardial lines" as being more expressive of what I take to be the origin of these shadows.

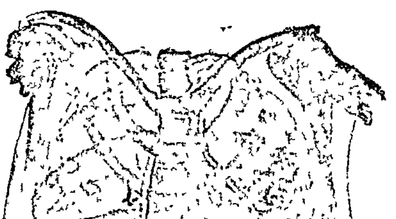
These streaks are not seen in every case, but when they occur recognition of them is important, for if their true nature be not realised they are very apt to be mistaken for evidences of disease, especially in a case in which "early" pulmonary tuberculosis is suspected

Other normal shadows are caused by the scapulæ. These can be largely eliminated by causing the patient to place both hands upon the top of the head and to rotate the elbows forward. This causes the scapulæ to turn edgewise and the upper part of the thorax is thus more clearly seen. Shadows cast by the scapulæ and clavicles can be recognised, if any doubt exist, by getting the patient to move the arms, when the shadows also are seen to move. Another somewhat triangular dense shadow presents itself in muscular subjects and is due to the large muscles of the shoulder girdle—*chiefly the trapezius and pectorales major and minor. This is* best seen when the patient is radiographed with outstretched arms, since this position causes the anterior axillary fold to become thicker. In females the mammary glands are sometimes represented by curved shadows.

On both sides of the median opacity a clear zone corresponds to each lung, which in health is transradiant from apex to base, thus allowing the posterior portions of the ribs, as well as the anterior, to be seen and producing a "lattice-work" effect Laterally the lungs are bounded by a darker line formed by the ribs where the shadows of these overlap In a few cases, especially in children, this line may appear as a dense black edge sharply limiting the inclosed area. The lungs brighten on deep inspiration, the varying degrees of transradiancy in the stages of expansion and contraction being probably for the most part due to the greater or less content of air at the time. Dr. Williams[9] attributes it, however, to the greater or less content of blood, for in comparing inflated with collapsed lungs removed from the body no such difference was noted by him. Inferiorly, the lungs are limited by a dark shadow with its convexity upwards, not dense enough to obscure the outlines of vertebral column or ribs. This rises and falls with the respiratory movements and corresponds to the diaphragm, below which shadows are cast by the liver and the spleen, a lighter interval appearing between these in some cases.

When the chest is examined with the tube anteriorly, to the left of the shadow cast by the vertebral column will be

FIG. 1 (*diagrammatic*).



Showing (*a*) "cardio-phrenic space" and (*b*) "pleuro pericardial lines" (tube posteriorly).

[9] The Roentgen Rays in Medicine and Surgery, 1902.

seen a semicircular pulsating shadow just above the base of the heart. This is termed the "left lateral bulge" and corresponds to the ascending part of the aortic arch. It is enlarged in aneurysm of that situation, or when displaced by the pressure of enlarged mediastinal glands. In a few cases a narrow triangular space is seen between the heart and the diaphragm, which lengthens and widens on deep inspiration but never extends so as to divide the shadows of the heart and the liver (see Fig. 1, *a*). Dr. Walsham formerly denied the existence of this space but now tells me that he has changed his opinion. I have repeatedly seen this appearance with the radioscope, but in the radiograph, owing to blurring due to movements of the heart and the diaphragm, it is more elusive. Since it is bounded by these organs above and below respectively I have given to this interval between the heart and the diaphragm the name of "cardio-phrenic space." I do not think that it has any pathological significance, for it is visible in many apparently healthy chests.

EXCURSION OF THE DIAPHRAGM.

The diaphragm is best observed with the focus-tube anteriorly, the screen being against the patient's back. The shadow in health presents two dome-shaped convexities, one on each side—that on the right being slightly higher than that on the left—and each half rises and falls after the fashion of a piston, symmetrically and rhythmically with expiration and inspiration. The text-books of physiology state that the diaphragm becomes flatter on inspiration: thus Sir Michael Foster[10]: "When at rest the diaphragm, drawn up by the negative intrathoracic pressure, presents a convex surface to the thorax; when contracted it becomes much flatter." So also Dr. E. H. Starling[11]: "When the muscular fibres of the diaphragm contract, two events occur, first, a lowering of the diaphragm; and second, a flattening of its circumference, which is thus drawn away from the chest wall." Other books on physiology follow suit. But, in point of fact, on radioscopic examination no flattening of the diaphragm is seen. The curve of the convexity on both sides is unaltered in descent, and each half—although attached to its fellow of the opposite side by the central tendon—by means of its own separate innervation through the phrenic acts quite independently. Taking the average of a large number of normal cases, I find that in quiet respiration the diaphragm moves half an inch on each side; but in maximum respiration the right side moves $2\frac{7}{8}$ inches and the left $2\frac{5}{8}$ inches, the right side having usually a wider excursion by about a quarter of an inch than the left.

UNILATERAL LIMITATION OF DIAPHRAGMATIC MOVEMENT IN PULMONARY TUBERCULOSIS.

After many and repeated observations I have found that loss of mobility of the diaphragm is the earliest indication of tuberculous mischief in the lung. Before any shadow due directly to the tuberculous process in the lung is visible the action of the diaphragm becomes evidently less on the unsound side. On looking up what few records there are on this interesting point, I find that Dr. Francis Williams[12] has published the following: "In many cases of pulmonary tuberculosis the range of movement of the diaphragm is shorter than in health; it does not descend as far as it should and this shortening of the excursion preceded in some cases the increase in density of the lungs and sometimes is one of the earliest signs of pulmonary disease." Dr. Bonnet-Léon[13] of Paris has not only reached the like conclusions but goes even much farther than I am prepared to admit. He states that, if diminution in the amplitude of the diaphragmatic excursions be observed, in the absence of any obvious cause one must always bear in mind the idea of commencing tuberculosis and must keep the patient under observation "in whom, some time later—90 times out of 100—will be found clear evidences of tuberculosis." To this impairment of diaphragmatic function Dr. Bonnet-Léon applies the term "diaphragmatic sign," and states that he meets with it at a time in the patient's life-history which he terms "the pre-tuberculous period." It seems to me that either a person has tuberculosis or he has not and that there is no intermediate stage such as this observer assumes. Hence I object to his term "pre-tuberculous" and would suggest that the tuberculous process has already begun; in other words, that the tubercle bacill are present and active although the process in the lung is not so advanced as to cast a definite shadow. I fail to see why in a healthy chest, even though its owner be "predisposed to tubercle" or of tuberculous descent, there should be unilateral diminished activity of the diaphragm. The cause of this early limitation of diaphragmatic movement has not yet been satisfactorily explained. One surmise is that it is due to unrecognised pleurisy which has left slight traces in the form of adhesions.

May not the cause be more reasonably assigned to a modification in some way of the inherent elasticity of the lung owing to the influence of the tubercle bacilli within it? Possibly some such process as the following takes place One apex does not expand as much as its fellow because its tissue vitality has suffered through toxic causes. Hence compensation is promoted in the lower lobe. But on account of the elasticity of the lung more muscular effort is required to obtain the additional expansion of the lower lobe which is necessary owing to lack of expansion in the upper. Hence it follows that want of descent of the diaphragm is mainly due to increased resistance to expansion on the part of the elastic tissue of the lower lobe on the affected side—that is to say, the deficient movement of the diaphragm is secondary to the lung condition. In out-patient practice one does not so frequently meet with pulmonary tuberculosis in this early stage, yet in a large proportion of cases which showed no resistance to permeability on screen examination, I have noticed deficient movement of the diaphragm on one side of the chest. In all these cases, of course, the ultimate test of tuberculosis is the finding of tubercle bacilli in the sputa. Unfortunately, this early stage cannot be illustrated by radiographs, for they would show nothing more than the appearances of any healthy chest, but the observations can be verified by anyone who takes a number of suspected cases without physical signs and examines them radioscopically.

LIMITATION OF DIAPHRAGMATIC MOVEMENT IN FIBRO-CASEOUS PULMONARY TUBERCULOSIS.

When the disease has progressed so that the characteristic stippled shadows are visible in the lung limitation of diaphragmatic mobility may become more pronounced or may decrease owing to compensatory hypertrophy of the muscle elements. It is a striking result that marked limitation may occur even when the apex only of the lung is attacked. This is probably due, as in the early cases, to toxic influences, but here there is in addition actual destruction of the lung tissue. In more advanced cases, moreover, where pain is a frequent symptom this cause, apart from other considerations, acts powerfully in inhibiting or lessening diaphragmatic movements. In the great majority of cases inflammation of the pleura coexists, as the pain may signify, and when the symptoms have become more chronic and adhesions have formed these also limit the action. MM. Kelsch and Boinon[14] examined radioscopically the chests of 124 young soldiers suffering from more or less simple ailments, not pulmonary. In 73 of these the examination proved negative; in 13 cases unilateral diminution of diaphragmatic excursion was apparent and in one bilateral diminution. In some cases the lungs were found to be in shadow, in others they were free. It is not possible to say that all the abnormal cases were tuberculous, for limitation may depend on other causes, but probably the greater number were so.

In the accompanying table are recorded the results of observations in 20 cases, and notes of Cases 2, 6, 8, and 10 will be found in the section on "Pulmonary Tuberculosis." Diminution in extent of excursion of the diaphragm will be noted in the great majority on the side most affected, the general rule being that in quiet and normal breathing the excursions are equal on the two sides, but on maximum respiration they are slightly greater in extent on the right than on the left side. The diminution referred to is well marked in Cases 3, 6, 13, and 18. Case 14 is interesting in that, although one of tuberculosis, the range of movement of the diaphragm is very much above the average. In Cases 6 and 12 the movement of the diaphragm was jerky and interrupted. In other cases undulatory movements have been noted. It is possible that these phenomena may be due to faulty innervation, the result of reflex irritation from the affected lung.

Table showing the Range of Mobility of the Diaphragm in 20 Cases of Pulmonary Tuberculosis.

No.	Sex.	Age.	Measurements in inches.				Remarks.
			Quiet respiration.		Maximum respiration.		
			Right	Left	Right	Left	
1	F.	24	⅝	½	2¾	2⅛	Early; left apex.
2	M.	35	¾	¾	1¾	1⅝	More advanced on the left side.
3	M.	27	1¼	1	2⅛	1⅛	More advanced on the left side.
4	M.	21	⅝	¾	2¾	2¼	Left fibroid; diaphragm one and a half inches higher on the affected side.
5	F.	24	⅝	¾	2⅝	3	More advanced on the right *side.*
6	M.	26	½	⅝	2	2⅝	More advanced on the right *side.*
7	F.	13	½	¾	2⅞	2⅝	Right side.
8	F.	33	½	½	2⅛	2½	More advanced on the right side.
9	F.	50	⅞	⅝	1¾	1½	Equal at both apices.
10	M.	30	⅝	¼	2¼	3	Early; more advanced on the right side.
11	M.	29	⅝	½	2¾	2½	Equal at both apices.
12	M.	44	½	¾	2¾	2¼	More advanced on the right side; diaphragm 2⅝ inches higher on the affected side.
13	M.	31	¾	1	1¼	1½	Late; more advanced on the right side.
14	M.	19	1¼	1⅝	3⅞	3⅝	Right apex.
15	M	32	⅞	⅝	1⅛	1¾	Left apex.
16	M.	31	⅜	½	1¾	1⅝	Both apices; more advanced on the right side.
17	M.	50	1	½	—	—	Both lungs; more advanced on the left side.
18	M.	33	½	¾	2½	2⅜	Both apices; more advanced on the right side.
19	F.	31	⅝	⅝	2¼	2¼	Right apex.
20	M.	25	⅜	½	1	1⅛	Both lungs, more advanced on the left side.

PULMONARY TUBERCULOSIS.

In the diagnosis of tuberculosis of the lung the Roentgen rays reach their widest and most practical everyday application. Aneurysms are comparatively rare; the insidious tubercle bacillus is with us always. Although observers may differ widely as to the interpretation of evidence based on tactile and auditory impressions, ocular evidence in most cases admits of no difference of opinion. Dr. Immelmann[15] of Berlin says: "We cannot rely upon percussion; its results are often in no proportion to the gravity of the disease. It may not give any indication in the very early stages of the malady, nor even of small cavities imbedded in the air-holding tissues of the lung. With auscultation it is not very different. No sound of respiration is characteristic of the phthisical process. We are in a position to give a definite diagnosis by clinical methods only when the tuberculous foci disintegrate and open into the bronchi and the possibility is offered of finding tubercle bacilli in the sputum."

Diagnosis to be of much service in pulmonary tuberculosis must be early. As Dr. Samuel Gee remarks,[16] "Therapeutics must begin before physical signs have developed, for if you wait for physical signs you wait too long." It is claimed that the Roentgen rays can detect tuberculosis of the lung at an earlier stage than any other means of physical diagnosis up to the present time at our disposal. In order to illustrate this I would take a typical patient in whom "early phthisis" is suspected and who comes up to the out-patient room with a slightly impaired note over one apex, over which area prolonged expiration is audible; nothing further can be ascertained except that the patient has a cough; he has not had hæmoptysis, he has not lost flesh, nor has he a family history of tubercle. This evidence, so far as it goes, is not sufficient to justify a diagnosis of pulmonary tuberculosis. This I say advisedly, because, although there is a difference of opinion on this point, some physicians being confident enough to give a definite diagnosis of tubercle on these signs alone, yet it should be remembered that at times a case of mitral stenosis presents many similar signs to those of phthisis at one apex, such as impaired note, prolonged and harsh expiration, and dry crepitations, resembling pleural crepitus (*most frequently* in the third left intercostal space), and yet no tubercle is found post mortem, the physical signs having been due to pulmonary embolism. The dry cracklings may be due to forcing of air out of the air vesicles in juxtaposition with the left auricle (Sansom, Walsham, Ormerod). If, however, the patient be examined then and there with the fluorescent screen a shadow of medium density will probably be seen obscuring the whole of the upper lobe of the lung on the side previously suspected. It is almost certain that pulmonary tuberculosis, which has gone far enough to cause physical signs, is never unilateral, and this point is brought out much more clearly [illegible] older methods. It is now [illegible] o-called "early phthisis" [illegible] erately advanced. In the [illegible][17] "A case presenting the ordinary first-stage symptoms of the out-patient room, if for our fathers an incipient case, is in our eyes an advanced case." If now we examine our typical case three months later we find that the shadow has gained in density, clouding over two-thirds of the lung on the side where the disease first became apparent, and over the upper half of the opposite side extends a similar but lighter mottled shadow. Still later evidences of [illegible] manifest and so [illegible] either by the radio [illegible] at stated intervals [illegible] check the course of the malady and early diagnosis being most important we have to ask: "At what stage does tuberculosis of the lung first give evidence of its presence to the fluorescent screen or radiograph?"

It may be taken as an axiom that tubercle bacilli cast no shadow on a photographic plate. Hence the earliest stage of invasion of the lung cannot be recognised except by impaired mobility of the diaphragm. The next pathological state is that of grey miliary tuberculosis and I have long tried to obtain a photograph to show acute miliary tuberculosis in the lung of a living subject but have not yet [illegible] too, was taken post mortem. Further investigation is yet required, but up to the present the evidence goes to show that tubercles in the lung cause no shadow until they have reached the "yellow" or caseating stage and then only in children or persons with very permeable chests. I have investigated the notes of one case, published in 1901 as "acute miliary tuberculosis in a child," radiographed during life, but found that there was no post-mortem evidence of tubercle in the lungs, the darker patches interspersed with lighter areas being due to broncho-pneumonia.

The typical shadow cast by "early" pulmonary tuberculosis is mottled or stippled. This appearance is characteristic and is simulated only by new growth, which latter is distinguished by the distribution of the shadows, peculiar physical signs, and the history. Other shadows, for which the tuberculous shadow may be mistaken, are those due [illegible] mammary [illegible] ese may be [illegible] regularity. [illegible] n the angle [illegible] not of their [illegible] moderate density and this is increased if the lung be congested, but the loss of permeability due to caseation throws a still [illegible] ented by cavities vary [illegible] whether empty or not. [illegible] er have been clearly seen during the [illegible] erified post mortem. A cavity at the apex or on the side nearest the focus-tube and close to the surface of the lung appears if empty as an area of unusual transradiancy. If full of pus or retained secretion, if imbedded in the centre of the lung or in a mass of consolidation, it may not appear, or it may be found lighter or darker than the surrounding tissue and, in such conditions, it is difficult to diagnose it with certainty. In many cases I find that cavities as seen by the x rays are smaller than the auscultatory signs indicate; in others the results obtained by each method separately closely correspond, this being usually, I think, when surrounding consolidation is small in amount. However damaged the base of the lung may become as a result of tuberculous infiltration, a clear triangular interval is always left between it and the diaphragm represented diagrammatically in Fig. 2 (*a*). This space corresponds to the lower part of the pleural cavity which the lung does not fill except on deep inspiration. Some observers state that the size of the heart is reduced and to this they attach some measure of diagnostic importance. As regards arhythmical tachycardia my observations are in accordance with those of Dr. Espina y Capo[19] of Madrid who says that this sign may be observed "in more than 94 per cent. of cases." In some moderately advanced cases shadows cast by enlarged bronchial glands are clearly visible and excellent radiographs illustrating this have been published. The shadows are irregularly disposed above the heart shadows, often causing apparent enlargement of the left lateral bulge. Calcareous glands appear as opaque nodules.

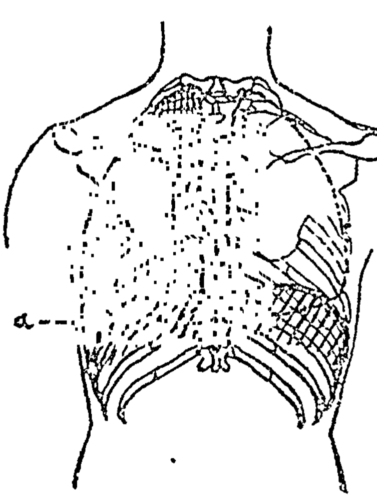
FIG. 2.



Showing clear space between lung and diaphragm.

The following four cases bring out various points in diagnosis, the numbers corresponding with those in the accompanying table.

CASE 2.—The patient was a man, aged 35 years, who had complained of cough for five months. There was no hæmoptysis but there were weakness and rapid loss of weight. A physical examination of the chest showed anteriorly deficient movement on the left side. The note was slightly impaired over both apices. Harsh irregular breathing and dry clicking crepitations were heard over the right side as far down as the second rib and over the left side as far down as the third rib. Posteriorly, the note was dull over both apices, over which harsh breathing was audible. There were dry crepitations at the end of inspiration over the right interscapular space. A radioscopic examination with the tube posteriorly showed in the right apex a dense shadow to the third rib and on the left apex a lighter shadow to the third rib. With the tube anteriorly it showed on the right apex a shadow down to the fourth rib and on the left apex an opacity at the apex shading off gradually to the fourth rib. There was "roof-tile" appearance of the ribs on both sides. The diaphragmatic movement was with quiet respiration three-quarters of an inch on both sides, while with maximum respiration it was one and three-quarter inches *on the right side and one and five-eighth* inches on the left side. In this case the signs to percussion, auscultation, and radioscopy correspond very closely.

CASE 6.—The patient was a man, aged 26 years, who had had hæmoptysis two years before. There was no cough, expectoration, or night sweats, but there was loss of appetite and of weight. Physical examination of the chest showed anteriorly an impaired note over the right apex and posteriorly dulness over the right side as far as the fourth rib. There was clear vesicular breathing all over the chest, with no added sounds. A radioscopic examination with the tube anteriorly showed the right side in shadow down to the fifth rib and the left side in shadow down to the third rib. With the tube posteriorly it showed the right side in shadow down to the third rib and the left side in shadow down to the second interspace. The diaphragmatic movement was with quiet respiration half an inch on the right and five-eighths of an inch on the left side, while with a maximum respiration it was two inches on the right side and two and five-eighths inches on the left side. In this case physical signs gave no indication that the disease was other than unilateral; radioscopy shows it to be markedly bilateral and more extensive on the right side.

CASE 8.—The patient was a woman, aged 33 years, who had complained of cough during the previous seven months with profuse expectoration. She had slight hæmoptysis on the day when she came to hospital. Her appetite was fair and there were no night sweats or wasting. A physical examination of the chest showed anteriorly dulness and bronchial breathing in the right front below the clavicle as far as the third rib. A radioscopic examination with the tube anteriorly showed on the right side a shadow as far as the fifth rib and on the left side a shadow as far as the third rib. With the tube posteriorly it showed a shadow at each apex as far as the clavicles and the first rib. The diaphragmatic movement was with quiet respiration half an inch on both sides, while with maximum respiration it was two and one-eighth inches on the right side and two and a half inches on the left side. In this case although physical signs only pointed to unilateral involvement yet on screen examination both sides were seen to be in shadows.

CASE 10.—The patient was a man, aged 30 years. He had no cough, but his expectoration was thick and there were night sweats and wasting but never any hæmoptysis. A physical examination of the chest showed, posteriorly, a prolonged expiration in the right scapular region. No other signs were discovered. Radioscopic examination with the tube anteriorly showed on the right apex a dense shadow to the fourth rib and on the left apex a light shadow to the fourth rib. The diaphragmatic movement was with quiet respiration five-eighths of an inch on the right side and three-quarters of an inch on the left side, while with maximum respiration it was two and three-quarter inches on the right side and three inches on the left side. This is another of these "early" cases which speaks for itself and shows how extremely valuable the Roentgen rays are. The chief points which established the diagnosis were the shadows and limited diaphragmatic mobility. Without the aid of the Roentgen rays this diagnosis could not have been made.

PLEURISY.

Acute pleurisy coming on for the first time, when in the dry stage, apparently casts no shadow. In pleuritic effusion appearances vary according to the nature and amount of the fluid contained in the pleural cavity at the time of examination. A purulent effusion yields a darker shadow than a sero-fibrinous effusion, the shadow in each case being homogeneous and of uniform density all over. Other conditions being equal, the heart is displaced to a greater extent when the effusion is left-sided, and in some cases it lies more transversely than normal.

EMPHYSEMA, BRONCHITIS, AND ASTHMA.

These three conditions are so frequently associated that I have grouped them under one heading.

Emphysema is indicated by brightness of the lungs as a whole; or, if only parts of the lungs be affected, by brightness of those parts. This brightness is intermediate between the normal clearness of the lung and the exceptional brilliancy seen in pneumothorax. Radioscopically, the typical "barrel-shaped" chest is seen, the ribs being raised into the horizontal position of forced inspiration. Whether this brightness be the result of more air or less blood in the lung must remain an open question. The vertical position of the heart should be noted; it is attributed to lowering of the diaphragm and increased lateral pressure on the part of the lungs. A skiagram taken laterally shows the apex of the heart to be no longer in contact with the chest wall, but expanded lung intervenes. This distance is probably as important a factor in causing

the heart sounds to be absent or muffled as is the interposed lung. A radiograph of a case of bronchitis would do equally well to illustrate the appearances presented by a normal thorax, hence this condition *per se* cannot be diagnosed by the x rays. The appearances presented in long-standing cases of asthma are similar to those of emphysema. In true emphysema and bronchitis the excursion of the diaphragm is limited in the upper part of its course; consequently the dome does not rise to the height which it reaches in health. In some cases of asthma, too, the action of the diaphragm on the affected side has been seen during the paroxysm to be inhibited. After the fit of coughing the affected half of the diaphragm ceases to be immobile and resumes its function. In compensatory emphysema of one lung, however, due to impaired function of the opposite organ, the range of movement is increased in both upper and lower halves.

PNEUMONIA.

In the early stages of pneumonia due to engorgement and exudation a light shadow is cast Consolidation is manifested as a dense shadow with ill-defined edges, or as opacity. In doubtful cases, especially where pneumonia be suspected, although there are no physical signs in the lungs the Roentgen rays are often of much service. By their aid the existence of a central patch of pneumonia may be revealed. In most cases they are the only means whereby a central pneumonia can be detected at all. The ribs on the unaffected side in a case of unilateral pneumonia are more horizontal than normal and the lung tissue bright, owing to hyperactivity of the sound lung which is practically doing the whole work of respiration. The shadow on the affected side is opaque, but the margin is not strictly limited, as in pleural effusion, but fades gradually away. Movement of the diaphragm in the downward half of its excursion is limited. When in any given case unilateral limitation of the diaphragm is observed we ought always to think of pulmonary tuberculosis, pleurisy, and pneumonia, for to one of these three causes the limitation is most often due. Restoration of diaphragmatic function is found by experience to be a more accurate test of the progress of the disease towards recovery than alteration of the physical signs or diminution of the opacity in the lung.

GANGRENE OF THE LUNG.

Pulmonary gangrene can be diagnosed from fœtid bronchitis by the x rays. Well-defined opacity reveals the existence of the former condition, an indication being thus given to the surgeon as to the site and extent of the gangrenous process which may be cured after costal resection and pneumotomy.

SUMMARY.

In bringing this subject to a conclusion I may say that I have endeavoured to present facts which have come under my own observation, as well as those noted by others, without any undue bias towards one or other method of physical examination. Many more illustrative cases might have been adduced and there are many interesting points upon which, for lack of space, I am unable to touch. It would appear at first sight as if the Roentgen rays presented a royal road to the art of diagnosis and that it is now no longer necessary to undergo much clinical labour in order to acquire manipulative and auscultatory skill: but this view is superficial and the value of the older methods is enhanced by the presentation to the eye of intrathoracic morbid appearances. Hence in many cases one method without the other is incomplete.

It is not claimed that the Roentgen rays are infallible, and, in fact, the like holds good of the older methods. In either case the greater the experience of the physician the more accurate should be his results In thoracic diseases especially even the most skilled are at times at a loss, and with the radiograph, as with the ophthalmoscope, not until one becomes accustomed to normal variations can a true judgment be formed of those in disease. Moreover, the lack of visual purple in the eyes of some renders them unable to see anything like as much in a skiagram as others can under equal conditions. A good radiograph in some respects may be said to resemble a painting by Turner. Without intuition or previous study the one is almost as incomprehensible as the other, but as we gaze the wealth of detail rises before our vision until finally we are able to interpret the meaning of streaks and shadows that to the untrained eye are meaningless.

CONCLUSIONS.

1. That the Roentgen rays form an important adjunct to the methods of physical investigation previously in use
2 That unilateral limitation of diaphragmatic movement, as seen by means of the fluoroscope, is often the earliest indication of commencing pulmonary tuberculosis.
3 That by the aid of the Roentgen rays pulmonary tuberculosis can be diagnosed at an earlier stage than by any other means at our disposal.

"Plusieurs fois, la radioscopie a révélé ce que les autres moyens de l'exploration physique avaient laisé inaperçu, ce que même ils ne révélaient pas après un nouvel examen" (Bouchard).

Ventnor.

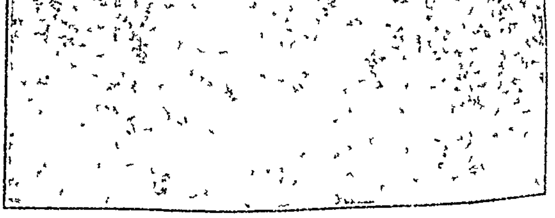
A BRIEF NOTE ON A BACILLUS IN A CASE OF ULCERATIVE COLITIS.

BY THEODORE FISHER, M.D., M R C P. LOND,
PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY; PHYSICIAN TO OUT PATIENTS TO THE BRISTOL HOSPITAL FOR SICK CHILDREN

BRIEF and imperfect though the following notes are, the bacillus to which they refer seems to me to have possessed features of sufficient interest to make it worthy of a short notice.

Cultures were taken from the liver of a man, aged 66 years, who had died from ulcerative colitis, where the ulceration of the large intestine was very extensive. Almost the whole of the mucous membrane from the ileo-cæcal valve nearly to the anus had disappeared, only little islets of swollen mucous membrane being here and there present which studded the exposed muscular coat like small polypi The cultures from the liver were taken on agar, gelatin, and glucose agar. At the end of 24 hours there was little growth in any of the media and for some reason they were not looked at again for another seven days. There were then marked gas formation in the glucose agar, a moderate amount of growth of apparently typical bacillus coli character on the gelatin, and a more scanty growth of similar character, but perhaps a trifle more translucent, on the agar. The agar culture was first microscopically examined To my surprise a growth similar to that of anthrax was seen The preparation showed felt-like masses composed of interlacing chains of bacilli. The segments in the chains varied considerably in length and also in breadth. No trace of branching could anywhere be seen. The growth decolourised when stained by Gram's method. The growth on the gelatin was composed chiefly of medium sized bacilli with rounded ends like the bacillus coli. Many of the bacilli had a barred appearance owing to irregular staining. Mixed with them were a few chains of bacilli which appeared to be the same bacillus as that which had grown on the agar. There were

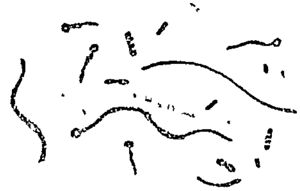
FIG. 1.



Culture from the liver on agar (eight days' growth), showing interlacing chains of bacilli.

o a few cocci present. The growth in the glucose agar s similar to that on the gelatin. Plate cultures were [illegible] on gelatin and the bacilli separated [illegible] h were a form of staphylococcus. [illegible] 1, however, on the original gelatin ture proved to be the same as the short bacillus sent in the plate cultures, since all sizes existed from ments long enough to stretch nearly across the field to rt, almost coccus-like bacilli. Although in cultures of out 48 hours' growth the filaments presented an unbroken e, in cultures four or five days' old they showed irregular [illegible] to the long threads [illegible] agar and gelatin [illegible] unfortunately the [illegible] There seemed to be no doubt, however, that the growth on gelatin, and presumably therefore the growth on agar also, was the bacillus coli. Lactose and saccharose as well as glucose were fermented. In passing it may be mentioned that the growth on saccharose agar showed bacilli of varied shape These were short round-ended bacilli, diplo-bacilli, and barred bacilli, and in addition to those numerous filaments, many of which had an enlarged spherical extremity at one end and a [illegible] In broth there was cloudiness [illegible] Numerous long form [illegible] th had the typical growth [illegible] of the bacillus coli. The [illegible] few in number. [illegible] coagulated It was interesting to note the persistence of the long forms After being grown successively on four different media during the space of two months the filaments were still present. It may be added that a similar growth was obtained from the spleen.

FIG 2.



Curious forms in culture on saccharose agar (48 hours' growth)

FIG. 3.

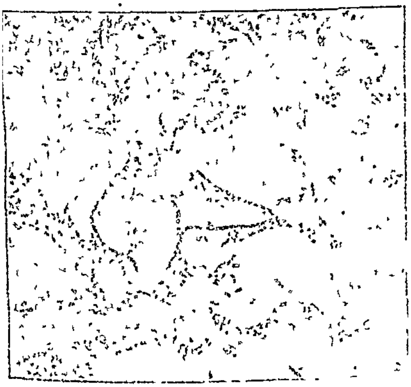


Plate culture on gelatin (48 hours' growth), showing filaments and bacilli of various lengths.

Although all the tests for the bacillus coli were not tried there can be little doubt that this bacillus was a variety of that micro-organism. Pathologists seem fairly well agreed as to the cause of acute dysentery, but the bacilli found in association with chronic ulcerative affections of the large intestine appear to have varied considerably in their nature. Varieties of the bacillus coli seem to have been the most common micro-organism found, and allowing that this bacillus is one of those varieties it has seemed to me that the curious felt-like character of the primary growth on agar is worthy of brief record. I have to thank Mr. George Brebner, lecturer on botany at University College, Bristol, for kindly taking the micro-photographs for me.

Clifton, Bristol.

THREE CASES OF CHOLECYSTECTOMY.

BY FREDERIC S. EVE, F.R.C.S. ENG.,

SURGEON TO THE LONDON HOSPITAL, ETC.

CASE 1.—The patient was a female, aged 25 years, who was sent to me at the London Hospital by Dr J Dunlop of Aveley on April 24th, 1898 On the previous day she was attacked with retching and sharp pain in the right side of the abdomen and noticed a swelling there. On admission the abdomen was somewhat distended. There was tenderness in the right hypochondrium and on palpation a rounded swelling, moving with respiration, was observed in the region of the gall-bladder. A diagnosis of local peritonitis due to empyema of the gall-bladder was made. Operation was performed as follows The abdomen was opened by an incision over the gall-bladder This was attached by recent adhesions to the omentum and transverse colon, both of which were deeply injected. The gall-bladder was distended and contained purulent fluid. No gall-stones were found in the gall-bladder or cystic duct, but on account of the patient's serious condition a prolonged examination was not made The gall bladder was drained. The patient was discharged at the end of a month, having still a small fistula. On Nov. 3rd, 1898, she was readmitted on account of the fistula remaining open. On the 14th I again opened the abdomen, separated the gall-bladder from numerous adhesions, and found a large stone in the cystic duct which it was impossible to move or to break up. The gall-bladder was therefore removed with the calculus and the wound was closed. Primary union ensued. The patient left the hospital on Dec 10th and continues in good health.

CASE 2.—A woman, aged 35 years, was transferred to my care by my colleague, Dr. Bertrand Dawson, in July, 1901. Her history was as follows Since Christmas, 1900, she had suffered with attacks of biliary colic. Four attacks occurred during the six weeks preceding admission. In April jaundice followed an attack of pain The patient was extremely stout, but on examination under chloroform Dr. Dawson could distinguish an ill-defined swelling suggestive of gall-bladder in the right hypochondrium. Operation was performed on July 5th. The abdomen was opened by an incision along the right linea semilunaris The edge of the liver extended about three inches below the costal margin, being drawn down by a greatly distended gall-bladder which was aspirated and then incised at the lower part of the fundus Several gall stones were impacted in the cystic duct and all efforts to dislodge or to crush them were unsuccessful Cholecystectomy was performed in the manner described below and a sleeve of peritoneum was then stitched over the end of the duct The abdominal wound was closed in the usual way. The progress of the case was uneventful Cultures showed that the fluid in the gall-bladder was sterile. She is at present quite well.

CASE 3.—A woman, aged 59 years, was transferred to my care by my colleague, Dr F. Warner. Her history was as follows. For three years she had suffered at intervals with attacks of colic, some of which were followed by jaundice During the last two months the attacks had been more frequent and the patient had hardly ever been free from pain. While in the medical wards she had one attack of pain and on one occasion her temperature rose to 100° F There was no jaundice. The liver was a little enlarged and the gall-bladder was not palpable Some rigidity of the upper part of the right rectus and local tenderness were present Operation was performed on Nov. 1st, 1901. [illegible] incision was made through the margin of the right rect[illegible] The gall bladder was shrunken [illegible] omentum, and attached to the transverse colon. In separating the adhesions the gall-bladder, which anteriorly was soft and rotten, gave way at its junction with the liver. On opening the gall-bladder it was found that the fundus and posterior surfaces were greatly thickened by fibrous tissue, being in places half an inch thick. It contained thin pus but no stones. The mucous membrane was thick, ulcerated, and covered with calculous material. The gall-bladder was removed. The abdominal wound was sutured and a drainage-tube was left in which was removed on the third day. Primary union took place; the subsequent progress of the case was uneventful.

Remarks.—The simplest manner of performing the operation of cholecystectomy is to incise the peritoneum covering the fundus of the gall-bladder at its junction with the liver. A finger can then be inserted between the gall-bladder and liver in the direction of the axis of the former. The separation is readily effected, practically without hæmorrhage. The reflection of peritoneum from each side of the gall-bladder on to the liver is then divided with scissors. This leaves the gall-bladder free. A cuff of peritoneum to cover the stump is preserved by incising this structure transversely on the under surface of the gall-bladder near the junction of the duct, stripping it upwards towards the hilum from the surface of the duct, which is then easily separated with the finger as high as may be necessary. A ligature is applied, the duct is severed, and the mucous surface of the stump is touched with pure carbolic acid. The cuff of peritoneum is sewn over the stump, but if time presses this may be dispensed with.

The indications for removal of the gall-bladder are already fairly well defined and need not be recapitulated. In the future I think it will be more often performed instead of drainage in cases in which the gall-bladder is thickened and contracted. It is quite evident that the gall-bladder is a structure which can be dispensed with without inconvenience, the chief difficulty being for the surgeon to assure himself that there are no stones in the common duct.

The indications for cholecystectomy are less evident when gall-stones are so firmly impacted in the cystic duct that they cannot be dislodged. The stones may be removed by incision and suture of the duct (Mayo Robson). The duct may, however, be ulcerated where the stone lay or there may be a cicatricial contraction above it, both being conditions likely to give rise to future trouble. Further, the operation of suture of the duct and subsequently of the wound in the gall-bladder to the parietes is likely to be more prolonged and I think more difficult than cholecystectomy.

Harley-street, W.

THE PREVALENCE OF PNEUMONIAS IN INFANCY.

BY S. VERE PEARSON, M.B CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL; MEDICAL REGISTRAR TO ST. GEORGE'S HOSPITAL.

MOST authorities on the diseases of infancy are now agreed that croupous pneumonia is by no means uncommon amongst infants. The knowledge of this fact, at one time the exclusive property of those who worked at hospitals for children, is even now not so generally recognised as it should be. The importance of realising it is evident at once when the prognosis of this variety of pneumonia is compared with that of broncho-pneumonia; for croupous pneumonia in infants has a good prognosis, while the prognosis of broncho-pneumonia is bad. It is essential, therefore, not only to differentiate the one variety from the other but also to have a correct idea with respect to their absolute and relative frequency. I am anxious to bring forward some data showing that croupous pneumonia is more common during the age of infancy than at any other succeeding age, an opinion somewhat at variance with that at present generally accepted. For, while authorities agree that croupous pneumonia occurs not infrequently at this time of life, they do not hold that it is more frequent then than at any other period of childhood. I shall attempt to show that during the first two years of life croupous pneumonia is not in order of frequency very far below broncho-pneumonia, which is admittedly much more prevalent during infancy than at any other succeeding period.

The prevalence of such a serious disease as br
pneumonia is well shown by the effect of its occurre
the general death-rate. The important part which i
in affecting the mortality of the community is indisp

[6] Practitioner, vol i., 1893, p. 434.

ast London Hospital for Children, Shadwell, where, howver, there is practically no restriction on the number of fants admitted, must be taken for what they are worth. sually 40 per cent. of the admissions into the hospital are atients under two years old. Moreover, the diagnoses for e most part were made by physicians not only well versed , but recognised authorities upon, the medical diseases infants—namely, by the then three senior physicians, r. Eustace Smith, Dr. J. A. Coutts, and Dr. Dawson Villiams. Now at Shadwell during the three years 1899–01 311 patients were admitted into the hospital suffering om croupous pneumonia. Of these 121—i e., 40 per nt.—were under two years of age, 137 were between two nd six years (a large proportion of these were patients etween two and three years of age) and 53 were between x and 14 years. It is obvious from these figures that mongst children the commonest age-period for croupous [illegible] y.

[illegible] of croupous pneumonia relative to [illegible] the Shadwell statistics it would eem—and here again my experience leads me to agree with e broad facts revealed by those statistics—that croupous neumonia in infancy is relatively to broncho-pneumonia [illegible] ed In a series [illegible] t 25 per cent. of [illegible], two years were [illegible] ias. Now in the ree years during which 121 patients under two years of age ere admitted for croupous pneumonia into the Shadwell ospital 230 cases of broncho-pneumonia were admitted. f these 172—i.e., 75 per cent.—were under two years of ge, 56 were between two and six years of age, and there ere only two patients older than six years of age It must o borne in mind that these figures are from a hospital where ery few infectious diseases are treated; and that conequently the relative frequency of croupous pneumonia [illegible] s actually the case. The [illegible] pous pneumonia, although [illegible] nonia in infancy, does not [illegible] of its occurrence.

[illegible] nce of the two common arieties of pneumonia in infancy is intimately wrapped up ith the distinctions between the two forms. Sometimes he primary broncho-pneumonias are difficult to differentiate rom the croupous pneumonias of infancy. In a paper[7] hich I read not long ago before the St. George's Hospital Hunterian Society I defined some of the chief oints upon which dependence must be placed in making he differential diagnosis between croupous and catarrhal neumonia in infants. But I was unable there to enter nto the question as to the separate entity of each isease. In his book upon the "Diseases of the Organs f Respiration" Dr. Samuel West has brought forward rguments in favour of classifying all the primary bronchoneumonias of infancy with croupous pneumonia. He advoates the restriction of the term "broncho-pneumonia" to the econdary forms only and holds that many of the primary orms are clinically cases of croupous pneumonia which take n pathologically the broncho-pneumonic lesion because the neumococcal inflammation is in an infant in whose ulmonary system there are anatomical and physiological eculiarities not present in the adult. It would be entering nto the question of etiology too much at the present moment or me to discuss this matter fully, but I can see no *a priori* eason why the pneumococcus cannot set up a true bronchoneumonia as well as a true croupous pneumonia. If roupous pneumonia in infancy really takes on the bronchoneumonic type of lesion we are seeking for a distinction where there is no real difference and it would be futile to liscuss either the differential diagnosis or the relative prevalence of the two conditions. But I do not agree with Dr. West on this point. To fall in with his opinion is not only inexpedient and uncalled for in the present position of our knowledge as to the etiology of the pneumonias but also dangerous to the precision and accuracy of our outlook upon the clinical aspects of these conditions. There would be a liability to lose sight of the important practical point—namely, the great difference in the prognosis of the two complaints—if this view were generally adopted. It is true that the very high mortality of broncho-pneumonia in infants is less in the case of the primary form than in the secondary; but its mortality rate never reaches that low limit which is associated with the croupous pneumonia of childhood. In practice some cases of pneumonia, diagnosed as croupous, more especially, of course, in those babies who die, are really cases of primary broncho-pneumonia; for in the primary broncho-pneumonia sometimes the disease spreads so rapidly and signs of consolidation become evident so soon that it may simulate very closely acute croupous pneumonia, especially should the signs be limited chiefly to one lobe. The likelihood of mistaking a primary broncho-pneumonia for croupous pneumonia is further rendered possible by its occasionally having a quite sudden onset, by its being sometimes associated with fever of the continuous type, and by the fact that it is usually of pneumococcic origin. But the opposite error of mistaking a croupous pneumonia in an infant for a broncho-pneumonia is equally common, and probably outside hospitals for children it is the commoner mistake. Moreover, another difficulty arises sometimes from the occurrence of intermediate forms. In the majority of these, in all probability, both varieties of pneumonia are present in different parts of the same lung or in opposite lungs at the same time. Dr. Coutts[8] points out that small secondary broncho-pneumonic patches may surround a consolidation of a truly croupous nature, that this is especially liable to occur in infants under two years of age, and that it is one of the most important ways in which difficulties arise in discriminating between the two varieties. But he maintains that "where the symptoms are well marked and typical and this, fortunately, is the case in a greatly preponderating majority of both forms, there is no difficulty in distinguishing between them."

In spite of these occasional similarities between the two diseases and the occasional difficulties in their diagnosis, however, they should never be confounded, for they differ essentially in their natural history, origin, incidence, course, histology, and especially in their clinical manifestations and prognosis. Dr. Pye-Smith[9] points out that because these two forms of pneumonia are occasionally difficult to differentiate the one from the other that is no reason why the attempt to do so should not be made in every case, nor any excuse for ever grouping them together either clinically or pathologically. As well might carcinoma and alveolar sarcoma or rubeola and morbilli be classified under the same head because sometimes they are almost indistinguishable.

The peculiarities of the pulmonary system of a baby no doubt explain satisfactorily why broncho-pneumonia is so common in infancy, why cases arise in which great difficulty occurs in the matter of diagnosis, why intermediate and mixed forms are found, and why broncho-pneumonia may come on as a complication of croupous pneumonia. But it seems to me unnecessary to claim that these peculiarities result in the croupous form of pneumonia taking on the catarrhal type in this class of patient, for I believe that the two types are as essentially distinct in the infant as in the adult. I maintain, then, that true croupous pneumonia is common in infants, that the primary broncho-pneumonias are in the majority of cases perfectly distinct from this, and that even those primary cases which occasionally simulate croupous pneumonia closely should be recognised as distinct from that disease and should not be classified with it but should remain in their present position amongst the broncho-pneumonias.

Serjeant's Inn, E.C.

RESPIRATORY CRISES IN GRAVES'S DISEASE.

BY J. GORDON SHARP, M.D. EDIN.

GASTRIC crises occurring in the course of Graves's disease are recognised and described, but I cannot recall any description of respiratory crises, yet I have met with at least two cases of very rapid breathing in which the exciting cause was evidently some poison set free in the system. The respirations succeeded each other with rapidity—not less than 60 a minute—the conditions being not unlike that seen in atropine poisoning. A peculiarity of the symptom is the marvellous action which opium, in some shape or other, has in slowing the respirations and restoring the patient to the normal well-being. In describing the two cases I shall omit all unnecessary details and confine my remarks to the salient points.

CASE 1.—A woman, aged 29 years, the mother of four children, had noticed a lump in the neck for two years, but had not suffered much discomfort till the onset of the present illness when she began to complain of palpitation, cough, and "difficulty of breathing." On inquiry and examination she was found to suffer from vomiting, cough, and pain over the larynx. The pulse was 210; tremor, moist skin, goitre, with throbbing vessels and exophthalmos were present, but the most marked symptom was the very rapid breathing. There was also a tickling cough which was referred to as originating in the throat. There was little expectoration. Half a drachm of paregoric and two minims of tincture of aconite in two tablespoonfuls of water were administered every four hours. The effect was marvellous. In a few hours the respirations fell to normal and the heart and pulse rates came down from 210 to 120, the usual frequency. The woman made a rapid recovery.

---

[7] Practitioner, April, 1903.

[8] Edinburgh Medical Journal, September, 1902.

[9] Cf. [illegible] Allbutt's System of Medicine, vol. v., p. 104

CASE 2.—A woman, aged 65 years, the mother of several children, had for years suffered from "spasms" at regular intervals. These attacks were referred to a stomach condition, but I have reason to believe that they were only crises in Graves's disease. She had no exophthalmos but she had an enlarged, throbbing thyroid gland and she had herself observed that the throbbing was always worst when the "spasms" were present. The other signs and symptoms of Graves's disease were observed—tremor, moist skin, palpitation, pulse 120 to 170, and laryngeal crises—but not till the present occasion had the patient suffered from a respiratory crisis. This was supposed to have originated in a "cold." Suddenly she complained of a so-called shortness of breath, although really the condition appeared to be as if some agent were stimulating the respiratory centre at the rate of from 60 to 66 times a minute. There was practically no cough and when the chest was examined nothing could be found to account for the respiratory trouble. The whole expectoration in the course of the night amounted to less than one tablespoonful of clear viscid mucus. At this time there were retching and some little vomiting of stomach mucus, but *vomiting was not a prominent symptom.* The patient was placed in a warm, moist atmosphere and the usual expectorant mixtures were tried for 48 hours and without benefit, as might be expected. The woman was becoming exhausted simply from the frequency of the breathing. At this period I gave her a one-grain opium pill, the time being midnight, and ordered another to be repeated in an hour. She slept for four or five hours and awoke practically well, and her respirations were reduced to 18 or 20. She bitterly complained that I had not administered the pills earlier.

In searching for an explanation of this increased activity of the respiratory centre I think I am justified in holding that in Graves's disease a poison is thrown into the system which under ordinary conditions is excreted by the ordinary channels and produces only the usual symptoms. Occasionally this poison is present in great amount and the ordinary channels are unable to deal with it sufficiently rapidly and the stomach is called in to aid and one gets then a gastric crisis. Less frequently the poison is present in great quantity or the excretory organs are unable to deal with it and the poison reaches the respiratory centre in great quantity and then one meets with respiratory crises. I know this view is open to objections, but it has the virtue of feasibility. Supposing it to be poison, then it belongs to the atropine, digitalis, or strychnine group as far as its action on the respiratory centre is concerned. Now, opium is *antagonistic to this group—that is to say, it has the opposite* effect on the respiratory centre—and hence its curative action in the condition which I have detailed.

BRITISH HOSPITAL, BUENOS AYRES.

A CASE OF LIPOMA OF THE CÆCUM.

(Under the care of Dr. JOHN O'CONOR.)

A WOMAN aged 45 years, was admitted into the British Hospital, Buenos Ayres, on Feb. 5th, 1900, with the following history. In October, 1899, she first complained of indigestion with some pain in the right abdomen near the which her medical attendant prescribed liquid diet mixture of soda, bismuth, and magnesia. She gr flesh and the pain became more intensified, accompanied flatulence, nausea, and a heavy feeling in the after food. On Jan. 3rd, 1900, she vomited for the time; afterwards this became a matter of frequent rence, but blood was not at any time observed in the matter. She had great difficulty in getting her bowels to the stools always appeared to be normal in character. 28th she felt a lump for the first time in the region she had previously complained of pain. On a distinct hard moveable tumour of about the size Tangerine orange was felt one inch below and to the of the umbilicus; it was tympanitic on percussion and tender to the touch. As general examination rev other organic affection the diagnosis seemed to pyloric tumour.

On Feb. 6th chloroform was administered and a incision was made through the right rectus; on op peritoneum a coil of large intestine presented, which out to be the ascending colon with a very moveable The latter contained a large ovoid mass which occupy its whole lumen. Taking into consideration absence of a doughy feeling and the immobility of swelling inside the bowel, a two-inch incision was made the cæcum. A gangrenous mass presented, which of sloughing mucous membrane covering a large fatty imbedded between the mucous coat and muscularis in a free zone of bowel wall. The gangrenous was liberally excised, the fatty tumour was enucleated, the cavity was as far as possible obliterated by The parts having been thoroughly irrigated the wound was closed by two rows of continuous silk and the cœliotomy one by tier sutures. An convalescence ensued and the patient left the hospital month later. When seen in October, 1902, she reported her condition had continued normal since the operation.

Remarks by Dr. O'CONOR.—As the above affection is somewhat rare, possibly the notes of the only case I have with in a series of over 1000 general abdominal may be of some interest. Taking into consideration the of the patient, the gradual onset of gastric symptoms, loss of flesh, and the site of the tumour, I was disappointed in not finding some serious lesion in pylorus. Yet on reflection the latter might been eliminated if full value had been accorded to the absence of gastric dilatation and the history of old stomach trouble.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Treatment of Aneurysm by Subcutaneous Injection of Gelatin.—A Case of Aneurysm of the Abdominal Aorta treated by the Introduction of Silver Wire.

A MEETING of this society was held on June 23rd, Mr. ALFRED WILLETT, the President, being in the chair.

Dr. GUTHRIE RANKIN read a paper on the Treatment of *Aneurysm by Subcutaneous* Injection of Gelatin. After alluding to the work done by Lancereaux and others in connexion with the cure of aneurysm by gelatin Dr. Rankin showed that though not universally accepted there was considerable evidence to prove that the results were due to an increased power of coagulability produced by the gelatin on the blood. The best results were obtained when the use of gelatin was combined with rest in bed, restricted diet, and iodide of potassium given internally. The method of treatment by gelatin subcutaneously had not so far been extensively adopted in this country. Lancereaux advocated the injection of 250 cubic centimetres of a saline solution containing 2 per cent. of gelatin and considered that a minimum of from 12 to 15 injections was necessary. Huchard preferred a 1 per cent. solution as being safer. In four cases treated by Dr. Rankin at the Dreadnought Hospital 100 cubic centimetres of a 2 per cent. solution of gelatin were injected at each sitting after the first and the average number of injections was 17. The inner aspect of the thigh was chosen as the most convenient situation for the operation. The solution consisted ne ounce of gelatin and 131 grains of chloride of sodium 0 ounces of sterile distilled water. Details were given of four cases treated, in three of which the aneurysm was acic, while in one it was abdominal. In all four cases e was more or less marked improvement. The following lusions were arrived at:—1. That gelatin injections, n with proper precautions, were safe. 2. That they luced alleviation of all the subjective and many of the ctive symptoms. 3. That the relief of symptoms was ably to be explained by shrinkage of the aneurysmal and consequent diminution of pressure on surround- parts. 4. That such diminution could be demon- ted in three out of the four cases treated. 5. That after-histories afforded evidence of the permanent re of the beneficial results of the treatment.—Dr. MAGUIRE had treated eight cases of aneurysm by tin injections. In seven of these there was considerable rovement; the remaining case was practically relieved re coming under his care. In one case an aortic rgitant murmur present at the commencement of treat- t disappeared after the third injection, showing that it [illegible] to disease of the [illegible] appeared ready [illegible] a course of six ks' treatment. He alluded to the advantages of gelatin ctions over the ordinary methods of medical treatment in referring to the risk of tetanus to which one of his ents succumbed he laid stress on the importance of ing the solution of gelatin for ten minutes, whereby the lity of tetanus spores, commonly present in commercial atin,' was readily destroyed. He attributed the rise of perature to the introduction of a foreign proteid into the [illegible] the risk of clot-formation else- [illegible] other arteries were diseased.— [illegible] experience of gelatin injections one case in which the injection was followed by a rigor h collapse and persistent vomiting for three days. The thod was not free from dangers other than the risk of tnus.—Dr. A. J. WHITING asked Dr. Maguire how long a iod intervened between the first injection and the onset symptoms of tetanus. He also asked whether the gulability of gelatin was impaired by boiling.—Dr. GUIRE, in reply to Dr. Whiting, said that one week psed between the first injection and the onset of tetanus l that boiling did not impair the coagulability of gelatin. Dr. RANKIN, in reply, said that in none of his cases were re symptoms at any time to cause anxiety. He had not erved coagulation elsewhere than in the aneurysmal sac.

Mr. D'ARCY POWER communicated a paper by himself and G. H. COLT on a case of Aneurysm of the Abdominal rta treated by the Introduction of Silver Wire with a cription of instruments invented and constructed to ilitate the introduction of wire into aneurysms. The ient was a man, aged 29 years, who had acquired philis at the age of 17 years and had only been ated with mercury for a short time. He had noticed pulsating swelling in the right side of his abdomen two and a half years and had been constantly der treatment. On five occasions he had received injec- ns of gelatin in the gluteal region without any marked eration in the progress of the aneurysm. The sac of e aneurysm was extremely thin in places and as the e of the patient seemed to be in danger it was deter- ned that the sac should be exposed and the artery from ich it sprang should be ligatured, or if this were im- acticable the sac should be filled with silver wire. The elling was diagnosed as an aneurysm of the cœliac axis or one of its branches. The sac was accordingly exposed d as it was impossible to isolate it 80 inches of silver re, with a clotting surface of 3·7 square inches, were roduced by means of an instrument devised and made Mr. Colt. The actual introduction of the wire only ok two and a half minutes and there was no trouble in sing the hole in the sac with a few point sutures. The tient had a good night after the operation and was fairly mfortable on the following day. His pulse continued to o, however, and he died 50 hours after the operation. The st-mortem examination showed that the aneurysm sprang om the abdominal aorta just below the diaphragm. The c was full of recently clotted blood in which the wire s entangled. On cutting across the aorta seven ches of the wire were found projecting upwards into e arch of the aorta. The rest of the organs were rmal and the heart was healthy except for a patch of adherent pericardium. The instruments invented and constructed by Mr. Colt were three in number. The first instrument worked on the principle enunciated in the following terms: "If what is known to the mechanical engineer as a milling tool be made to revolve at a less distance than the diameter of the wire employed from the inner surface of the dorsal wall of a hollow tubular needle, the ventral wall of which has been cut away, the milling tool will grip the wire between itself and the needle and will wind it off the reel and drive it through the needle with a force only limited by the force at the disposal of the operator. It will, at the same time, snag or mill the wire." To carry out this principle a quarter-curved tubular needle was imbedded for about two inches of its length in the substance of a brass carrier. A semicircular incision was then made down to it through the brass so that the lumen of the needle was exposed. A milling tool was introduced at this spot to compress the wire with a steady grip as it passed through the needle, the pressure being made between the milling tool and the dorsal wall of the needle. The mounting of the needle was then bolted to the mounting which carried the milling tool, and it was then so geared up as to give the operator room to use the instrument without getting his hands too near the wound. A second hole was made in the tubular needle distal to the milling tool, and along this a stiletto was passed to block the hollow needle to its point whilst it was being pushed into the sac of the aneurysm. The instrument was further provided with a handle by which to hold it and with a second handle to revolve the milling tool. The second instrument differed in many important respects from the first. There were no gear wheels and the milling tool was driven direct. The needle was sufficiently long to remove the mechanism to a distance from the wound and the instrument was capable of taking a thinner wire than that taken by the one first invented. No stiletto was required and by an ingenious but simple device the wire, which was introduced in coils, could be divided into lengths at the will of the operator without withdrawing the needle from the sac of the aneurysm. Another method of wiring aneurysms consisted in the introduction of one or more cages of steel wire. These cages were so constructed as to form cylinders when they were compressed and the cylinders could be passed through a fine cannula into the sac of an aneurysm where they would immediately expand. The paper was illustrated by the epidiascope.

OPHTHALMOLOGICAL SOCIETY.

[illegible] Fistula Formation in the Treatment of [illegible] sarcoma of the Upper Lid.— [illegible] is Palpebrarum Muscle.

AN ordinary meeting of this society was held on June 11th, Mr. WILLIAM W. LANG, the President, being in the chair.

Major H. HERBERT, I.M.S., read a paper on Subconjunctival Fistula Formation in the Treatment of Chronic Glaucoma, either by producing a subconjunctival prolapse of the iris or by infolding the conjunctiva. The report dealt with 130 cases in which iris was left prolapsed under a conjunctival flap and in all but 18 eyes a small iridectomy was combined. A large number of these eyes were in an advanced stage of the disease and were therefore not very hopeful when an iridectomy only was done. For this reason a large incision was dangerous. The visual results of operations done from six months to upwards of three years previously were given. Only one eye had suffered from late infection and this gave way rapidly to treatment. In two eyes there was iridocyclitis immediately following the operation. In one case it caused partial occlusion of the pupil and in the other, which was somewhat neglected, it led to sympathetic ophthalmia with total loss of both eyes. The sight of another was lost through protracted delay in filling of the anterior chamber. These serious early complications were less numerous than when simple iridectomy was done. It was claimed that a filtering cicatrix could be obtained with certainty and that in some cases this was the only way to relieve the tension. At any rate, the risk was far less than if the tension was not relieved by the iridectomy. On the whole, the visual results were much better than could have been expected from typical iridectomy. Many cases of so-called atrophy of the optic nerve after operation were in reality due to unrelieved tension. A fistulous cicatrix was indicated (1) when iridectomy had already failed;

(2) where it was likely to fail, such as in advanced cases; and (3) when the patient was not expected to return for a second operation if one was required. The danger to the other eye was very remote and would probably yield to mercurial treatment or enucleation. The connexion of the iris with the prolapse could, if desired, be severed by a subconjunctival sclerotomy, cutting up through the attached base of the iris. The second method, by a subconjunctival infolding into a small sclerotomy wound, had proved effective in a number of cases. The aim was to establish a fistula unconnected with the uveal tract. By a special suture the flap could be kept in place long enough to keep separate the lips of the wound so as to form a permanent subconjunctival fistulous tract. The ten cases in which this was done were of too recent date to give a correct appreciation of its value. Other successful cases of conjunctival infolding without suture had been under observation for periods up to nearly two years. Many other attempts, however, failed to relieve tension through the flap not remaining infolded long enough; and in one eye the tension was far too much reduced. Apparently infective mild iritis came on and eventually detachment of the retina. 23 operations were performed without suture or with imperfect suture.—Mr. Priestley Smith, Mr. E. Treacher Collins, and Sir Anderson Critchett made remarks, and Major Herbert briefly replied.

Mr. H. Work Dodd communicated a paper on a case of Melano-sarcoma of the Upper Lid. The patient was a woman, aged 83 years, who had noticed a lump in the upper lid for six weeks. There was no pain at first but latterly there had been some. The tumour was situated in the centre of the upper lid and was of about the size of a hazel nut; there was no redness, œdema, or tenderness. On the under surface the growth was soft, jelly-like, and vascular. The eyeball was almost hidden by the growth but its movements were free. The patient had several wart-like growths about the body. The contents of the orbit were removed, the lower lid alone being left. A Thiersch graft was afterwards applied. Only 45 cases of primary sarcoma of the eyelid had been recorded: ten were melanotic and four of these originated in the palpebral conjunctiva. Van Duyse stated that: (1) of the few arising from the palpebral conjunctiva most were pedunculated, while those from the skin or mucous membrane were papillary in form; and (2) these attained a considerable size before extending into the surrounding tissues. In this case the tumour was pedunculated and it had affected chiefly the free surface, leaving the skin, orbicularis muscle, and tarsal plate intact and healthy. All these circumstances pointed to its origin being in the palpebral conjunctiva.

Mr. N. Bishop Harman read a paper on Innervation of the Orbicularis Palpebrarum Muscle. He outlined the observations which had led Mendel to the formulation of his hypothesis "that the frontal and orbicularis muscles, although peripherally supplied by the facial nerve, were 'eye muscles' and form the 'oculo-facial' group whose central innervation is the oculo-motor nucleus." He contended that the operation of excising these muscles in young animals which had been followed by a diminution of the cellular elements of the third nerve nucleus did not prove that the lost nerve cells were the central connexions of the nerve to the excised muscles, for by the very conditions of Mendel's operation—by the stitching the eyelids together—he had interfered with at least one proper eye muscle connected with the third nucleus, the levator palpebræ superioris, into the region of the nucleus of which Mendel sought to attach the orbicularis. Mr. Harman traced the ancestry of these facial muscles. In man there were superficial and deep layers of muscles more or less differentiated owing to the vigorous facial action of man; in lower animals—for example, lemurs—there were simple muscle sheets. In the sharks the earliest representatives of these muscles were found in connexion with well-developed eyelids and nictitating membranes. By an embryological investigation he had shown that these muscles were primarily the muscles of the spiracle gill which had been dragged forward for the service of the eye. In these fish the innervation was from the facial complex, the nerve proper to this gill. By reference to the work of Gaskell, which pointed out the different values of segmental nuclei, he showed how difficult it was to conceive the transference of the innervation of a "splanchnic" muscle from a splanchnic nerve and a splanchnic nucleus such as the seventh to a somatic nucleus such as the third; the thing was without parallel. In the phenomenon not rarely found in man, that of "associated jaw-winking movements," of which he exhibited a case, there was evidence th arrangements found in the fish still held good for ma these cases there was partial ptosis of one upper li putting into action the external pterygoid of the sam the eyelid was promptly elevated. This he showed "atavistic anomaly," the occurrence of that asso movement between jaw and gill which was always seen breathing of fishes. When the mouth of the fish open operculum covering the gills was relaxed. In these c jaw-winking movement in man, when the deep gill (pterygoid) contracted there was an associated relaxa the superficial gill muscle (orbicularis) which allow weak levator to pull up the lid.

Anatomical Society of Great Britain Ireland.—The summer meeting of this society was Liverpool on June 19th and 20th. The scientific proce included the exhibition of a large number of specin the practical anatomy rooms in University Colleg several papers and demonstrations which were given lecture theatres. Amongst the exhibits were the ing: models prepared by Professor Patten, illustrati Visceral Anatomy of the Hainan Gibbon and the T and Abdominal Viscera in Man; a model prepared F. W. Jones from sections of an early Human E a series of Radiographs prepared by Dr. C. T Holland and Dr. David Morgan; specimens of the Ci Willis, prepared by Dr. R. E. Kelly; the Brain an Photographs of the Cord of the Porpoise, by Dr. Wat and a specimen of the Human Lung, by Dr. T. R. Br who exhibited a number of preparations and dr made by Dr. A. T. H. Waters when writing his Fothe Prize Essay for 1859 on the Anatomy of the Human The preparations showed the arrangement of the a branching off from the terminal bronchial tubes. attention was drawn to Dr. Waters's observations proved at that early date that the blood in the br arteries returned to the left side of the heart b of the pulmonary veins and not to the righ by the bronchial veins, which merely returned from the structures at the root of the lung.—Dr. Bryce, whose work in connexion with karyokinesis known, gave a lantern demonstration of the Cells Embryo of the Lepidosiren.—Professor J. Symington forward some further work on the Relations of the Parts of the Brain to the Surface, a subject on which been engaged for some time past.—Professor A. T gave a most interesting and highly suggestive paper Evolution of Man's Cranial Form which he illustrat some ingenious models. The paper gave rise to an e discussion, in which Sir William Turner, Professor Cunningham, Professor G. D. Thane, and many othe part.—The work on June 19th terminated with account of the important investigations now bein out by Dr. A. W. Campbell of Rainhill Asylum, Lan which showed that there existed in the cerebral c direct correlation between physiological function and logical structure.—On June 20th Dr. O. Addi-o some further information on the Surface Marking Abdominal Viscera.—Professor Arthur Robinson some specimens illustrating the Development of the the Cranium and gave a brief outline of the conclus which he had arrived; he also gave the results of his vations on the Development of the Vitreous Body.—P A. H. Young and Dr. Peter Thompson read a paper with the Development and Morphology of the Renal A with Horseshoe Kidneys, and with the Ventrally-s Pelvis of the Ureter, of which deformity they showed specimens.—Mr. Lickley read a paper on the Relation Seventh and Eighth Ribs to the Sternum in Man.— Cameron gave a lantern demonstration of Secti Amphibia which showed the pineal body to be d mentally an amesial structure.

Plaistow and Canning Town Medical So —A meeting of this society was held on May 27th, Mr. Rose being in the chair.—Mr. J. Jordan Harvey ex a Large Bi-lobed Placenta, the cord being inserted junction of two equal lobes.—Mr. Rose showed tention Cyst of the Choroid Plexus.—Dr. L. A. delivered an address on Acute Abdominal Cases in G Practice in which he pointed out the extreme diffic diagnosis which these cases at times presented. He the importance of early and exact diagnosis and concisely the points of value in determining the question of operative treatment.—A short discussion followed and a hearty vote of thanks to Dr. Smith for his very practical address brought the proceedings to a close.

Reviews and Notices of Books.

A Treatise on Diseases of the Eye, Nose, Throat, and Ear for Students and Practitioners. By Various Authors. Edited by WILLIAM CAMPBELL POSEY, A.B., M.D., Professor of Ophthalmology in the Philadelphia Polyclinic; and JONATHAN WRIGHT, M.D., Laryngologist to the Brooklyn Eye and Ear Hospital. London: H. Kimpton. In two volumes, large 8vo. Vol. i., pp. vi. + 689; vol. ii., pp. 549. Price 32*s. net.*

THE plan of dividing a text-book into chapters or sections and confiding each division to a separate writer, with strict limitation of space, is from many points of view a good one. It has the disadvantages of some overlapping and of some want of unity, but these defects are more than compensated by the possibility of selecting authors who are well versed in the subjects assigned to them and are therefore qualified to speak with the authority of experience and who, as a rule, are not unwilling to compress into a reasonable compass the results of their reading and practice.

The first volume of this imposing treatise is devoted to the eye and is divided into 15 chapters, each from the pen of a different writer. It is illustrated by 19 plates and 358 woodcuts. The type is clear and good and the book contains singularly few clerical errors. Amongst the contributors we are glad to see the names of Mr. W. T. Holmes Spicer, one of the ophthalmic surgeons at St. Bartholomew's Hospital, London, who has undertaken the important chapter on Diseases of the Retina, Optic Nerve, and the Cerebral Origin of that nerve, and of Mr. E Treacher Collins of the Royal London Ophthalmic Hospital, by whom the chapter on Glaucoma has been written, a subject to which, amongst others, he has devoted much attention. A Canadian surgeon, Dr. R. A. Reeve, describes the Diseases of the Orbit, Lacrymal Apparatus, and Lids, and the remaining chapters are written by American surgeons, Dr. W. C. Posey of Philadelphia discussing the examination of the eye; Dr. W. N. Suter of Washington, the physiology of vision; Dr. A. Duane of New York, refractive errors in general; Dr. Casey A. Wood of Chicago, the motions of the eye and their derangements; Dr. John Weeks of New York, the diseases of the conjunctiva, cornea, and sclera; Dr. H. von Würdemann of Milwaukee, the embryology of the eye, the anomalies, diseases, and injuries of the iris, ciliary body, choroid, and vitreous; Dr. H Gifford of Omaha, Nebraska, sympathetic ophthalmia; Dr. E. C. Ellett of Memphis, Tennessee, diseases of the crystalline lens; Dr. Elmer G. Starr of Buffalo, New York, disturbances of vision without apparent lesion; Dr. C. F. Clark of Columbus, Ohio, the eye in its relation to general diseases; Dr. Clarence Veasey of Philadelphia, general preparation for operations upon the eye; and Dr. Edward A. Shumway of Philadelphia, the technique of the pathological and bacteriological examinations of the eye.

It is difficult within the limits of a review to refer to more than one or two of the chief divisions into which the whole of ophthalmology has here been cast, but as special attention is called in the preface to the chapter on the Eye in its Relation to General Diseases by Dr. C. F. Clark we turned to the pages of that essay and can recommend its perusal to every student and practitioner. Dr. Clark commences with "anæmia" which, he points out, is secondary to so many and such diverse pathological conditions that it is necessary to observe caution to avoid confusing the effects of anæmia proper with those of the disease on which it depends, and he believes that there is probably no one constitutional condition which more frequently plays a part in producing the various forms of asthenopia He has little doubt that the early and judicious use of those means—hygienic, dietetic, and medicinal—which tend to overcome anæmia could in a large number of instances delay for many years the necessity for correcting the low grades of hyperopia and astigmatism which are so important a feature in the practice of ophthalmology as seen in America. With this view we are quite in accord. At the *same time* the young American is probably more sensitive to slight defects in the refraction of the eye than the average European child or youth and he complains and seeks for relief at an earlier period. It is only gradually dawning on school teachers, and still more slowly on parents, that a low position in class of an otherwise intelligent child is dependent on imperfect vision as a rule and it is long before it is found convenient to take the child to an ophthalmic hospital or, when they have been ordered, to obtain the necessary glasses. The following remarks, too, are dictated by good sense and express well what has passed through the mind of every ophthalmic surgeon of experience. "The general asthenia which accompanies the anæmic state manifests itself as asthenopia, and this may be conjunctival, ciliary, muscular or retinal. It not unfrequently happens that after a prolonged struggle on the part of the ophthalmic surgeon to correct properly hyperopia, astigmatism, and muscular imbalance by means of spherical, cylindrical and weak prismatic lenses, and to relieve obscure reflex symptoms such as headache apparently due to eyestrain and obstinate photophobia and conjunctival irritation by appropriate treatment, it is found that large doses of a ferruginous tonic and a properly regulated life, with an abundance of out-of-door exercise, bring about complete relief from all the distressing symptoms, rendering glasses for the time being unnecessary. On the other hand it frequently happens that all of the best directed plans of general treatment completely fail when they are not supplemented by the most painstaking correction of all such errors of refraction and muscular imbalance." Dr. Clark discusses the affections of the eye associated with diseases of the vascular, respiratory, and digestive organs, and with the urinary, sexual, cutaneous, and nervous systems, and gives a good account of the relations of the eye to syphilis, which disease, it appears, only produces absolute loss of sight in about 2 per cent. of cases of blindness from all causes.

The chapter by Dr. Casey Wood on the Motions of the Eyeball and their Derangements will, if read carefully, supply all requisite information in regard to the defects of mobility which, formerly designated outward or inward, convergent or divergent squint, have been re-named collectively, heterotropia, and more precisely differentiated under the terms of esophoria, exophoria, cyclophoria, anaphoria, cataphoria, and the like. The symptoms and pathology of each form are given in detail. Dr. Wood approves, in cases where shortening of the muscle is required, the method devised by Dr. Frank Todd of making a "tuck" in the tendon, for the accomplishment of which a specially formed instrument resembling a pair of forceps with crossed legs is used.

Dr. Weeks, in his instructive chapter on the Diseases of the Conjunctiva, Cornea, and Sclera, adopts a new classification of conjunctivitis, dividing the varieties of this disease into the specific forms typically represented by gonorrhœa and diphtheritic conjunctivitis and the non-specific forms in which no specific cause has been hitherto recognised, as may be observed in simple and follicular conjunctivitis and in trachoma. An excellent drawing, after Orth, of the microscopic appearances after double staining of a section of trachomatous nodules is given and there are also useful drawings of the micro-organisms that have been found in various affections of the conjunctiva.

The subjects of Diseases of the Crystalline Lens and Cataract are treated by Dr. Edward Ellett at considerable length and very sensibly. No space is wasted in describing in wearisome detail the various forms and modifications of opacities of the lens, but after a few pages devoted to the structure of the lens, its embryology, the congenital anomalies which it presents, and the effects of wounds and injuries, the author proceeds at once to the consideration of cataract. The changes that may be observed in the structure of the lens are given and are illustrated by some excellent micro-photographic drawings from sections made by Dr. E. S. Thomson of the Manhattan Eye and Ear Hospital. In regard to the treatment of cataract Dr. Ellett considers "absorption treatments" and the administration of drugs to be futile measures, though alteratives may be occasionally beneficially prescribed. He thinks the utility of "ripening operations" in cases of immature cataract to be questionable. He assigns reasons which render it, in his opinion, advisable to operate on one eye, notwithstanding that the other is clear. He considers that the safest mode of operating for extraction is a preliminary iridectomy followed by removal of the lens after some weeks. The account of the accidents that may occur in the course of the operation is good and complete. The strength of the solution of cocaine to be instilled into the eye should have been given. We have known a 20 per cent. solution to be used by a nurse unaccustomed to ophthalmic operations with disastrous results. A 4 per cent. solution dropped in at intervals of half a minute for five minutes is usually sufficient to secure complete insensibility. The great importance of an exceedingly sharp knife in facilitating the operation might have been also insisted upon. Scarcely sufficient stress is laid upon the danger attendant upon the operation of needling the capsule in cases of secondary cataract. Dr. Ellett only remarks by way of warning that "provided the vision is not better than $\frac{20}{60}$, and the reduction of vision is not manifestly due to some other cause, the membrane should be divided," and various modes of dealing with it are described. It might easily be regarded by the young practitioner as a trifling operation that may be undertaken, providing no inflammatory symptoms are present, without misgiving. But the practised ophthalmic surgeon is well aware from bitter experience what dangers lurk in the simple proceeding of needling. Many a surgeon and many a patient have reason to regret that they had not left "well alone," and the dangers as well as the appropriate treatment might have been given, we think with advantage, in fuller detail.

In conclusion, we consider that amongst the many treatises on ophthalmology that have been recently published Vol. I. of Dr. Posey's and Dr. Wright's Diseases of the Eye, Nose, Throat, and Ear will occupy a distinguished place and may be regarded as an authoritative and altogether trustworthy exposition of the present condition of ophthalmology in the English language. We shall consider Vol. II., which deals with the Nose, Throat, and Ear, in a future issue.

Physical Chemistry: for Physicians and Biologists. By Dr. Ernst Cohen, Professor of General and Inorganic Chemistry in the University of Utrecht; authorised translation from the German by Martin H. Fischer, M.D., Instructor in Physiology in the University of California. New York: Henry Holt and Co. 1903. Pp. 343.

None can dispute the importance of a knowledge of physical chemistry if the great cause of medicine is to be advanced and happily there are signs of medical men becoming convinced of this fact and in accordance with this conviction of giving that attention to the subject which it demands. The present volume has been written in response to the request of a number of physicians to give in a series of lectures a *résumé* of those subjects in physical or general chemistry which are of importance in medicine. In all there are 14 lectures and the subjects comprise reaction of velocity, equilibrium, osmotic pressure, the molecular weight of dissolved substances, cryoscopy, and the theory of electrolytic dissociation and its applications. In a word, we find in this volume the scientific interpretation of well-known physical conditions and facts and as the nature of these becomes more understood so we may hope will treatment become less empirical. A drawback to the study of the exact scientific aspect of many physiological questions for the general practitioner, however, exists in the fact that a certain amount of mathematics must be studied and not every person has a mathematical mind. We do not know, however, a more suitable book to recommend than the one before us to those who are bent on possessing an accurate scientific idea of the many phenomena taking place in the human machine.

The Elements of Experimental Phonetics. By Edward Wheeler Scripture. London: Edward Arnold. New York: Charles Scribner's Sons. 1902. Pp. 627 and 26 Plates. Price 21*s.* net.

In this book Mr. Scripture has brought together a very large body of facts bearing upon the study of speech and the work is original in the sense not only of placing the author's own observations on record, but in the still more important sense that it gathers and focuses rays from many and widely separated lines of inquiry, thus bringing to light a new object of research. The mechanism of sound records, such, for example, as the Marey tambours, the gramophone, sensitive flames, and the like, forms one large division of the work. Another is devoted to the physiology of hearing and in close connexion with this comes a third branch—namely, the psychology of the perception of sound. A fourth division of the work is concerned with the mechanism of speech—that is to say, of the organs of speech—and treats incidentally of the anatomy of the mouth, the nose, and the pharynx; and a fifth deals with phonetics strictly so-called, that is to say, the elementary sounds, interruptions, and other audible signals of which vocal speech is built up. On all these subjects the author has read widely and to very good purpose and his book will form a worthy addition to the bicentennial publications of the Yale University. Indeed, to the study of its subject it is an indispensable aid. But it betrays haste in its preparation—as is perhaps natural in a work published under pressure of a ceremonial occasion. Experiments are described in great detail even when they are, as we may say, only half translated. For example, a large proportion of Mr. Scripture's experimental facts are drawn from German observers and need much explanation to render them intelligible to English readers. Thus the association of ideas is illustrated by the imperfect appreciation by a German experimenter of a German word half seen or incorrectly heard. Such experiments can be followed only at a great distance by an ordinary English reader and should be repeated for his benefit with the assistance of an English subject and English speech. The same kind of incompleteness runs through the entire work. A copious use of phonetic symbols—letters turned upside down and such-like conventional signs—is, of course, indispensable in such a work. But these symbols need explanation and receive much less than they require. An explanatory table appended to the book does something for the reader in this respect, but grudgingly. For instance, few readers will be greatly helped by the explanation that the symbol ɸ (printed in grotesque style as here) represents the Japanese "f," but Mr. Scripture vouchsafes no more. This is but an extreme instance of the obscurity, due to deficient explanation, which renders much of the book more or less unintelligible, and to such an extent as to be a serious flaw. But that notwithstanding, we have here a valuable contribution to a difficult and comparatively neglected line of study to which all students of the mechanism of speech will hereafter have recourse and from which much useful information and many illuminating hints may be drawn both by medical men to whom the phenomena of speech are symptoms and by teachers of languages to whom they are items in "the daily round, the common task."

La Gastro-enterostomia, Metodi Operativi, Indicazioni, Risultati. (*Gastro-enterostomy, Methods, Indications, and Results.*) Da Dott. ARISTIDE MATTÒLI, chirurgo primario, direttore dell' Ospedale Civile di Tolentino. Con 65 figure intercalate nel testo. Roma: Società editrice Dante Alighieri di Albrighi, Segati e C. 1903 Pp. 330. Price 7.50 lire.

THERE is no operation on the stomach which is of more importance than gastro-enterostomy. It is now the operation which is preferred in the greater number of the diseases of the stomach which come under a surgeon's treatment and yet it is comparatively new. In 1881 Wölfler started to perform a pylorectomy for a malignant growth of the pylorus, but found that the tumour was so extensive and adherent that it was not possible to remove it. Nicoladoni, who was assisting at the operation, suggested that an anastomosis should be made between the stomach and the small intestine This was done and the patient recovered from the operation but died four months later from cancerous cachexia. At first only performed for irremoveable growths of the pylorus gastro-enterostomy has now come to be employed for many other conditions, and Dr. Mattòli gives 11 conditions for the relief of which it may be performed. They are malignant disease of the pylorus, cicatricial contraction of the pylorus, narrowing of the pylorus from extrinsic causes, syphilitic or tuberculous disease of the pylorus, congenital pyloric stenosis, gastric ulcer, ulceration or narrowing of the duodenum, hour-glass stomach, gastroptosis, gastric dilatation, and severe dyspepsia. An operation applicable to so many conditions deserves careful study and the author has collected in this volume an account of all the methods which have been employed; he also gives very elaborate statistics of the operation. In all he has collected 1028 cases, of which 819 recovered. Dr. Mattòli has had 17 cases of his own and all of them were successful. The work is very thorough and is by far the best treatise on this valuable operation, though, unfortunately, it is only available to those who can read Italian. We may mention that the printing of the book is excellent.

An Atlas of Illustrations of Clinical Medicine, Surgery, and Pathology. Compiled for the New Sydenham Society (a continuation of the "Atlas of Pathology"). Fasciculus XV. (Double Number), or III. and IV. of the New Series: Xanthelasma and Xanthoma, with special reference to their association with Functional and Organic Diseases of the Liver. Plates A to M and XCII. to XCVII. London: The New Sydenham Society. (Agent, H. K. Lewis.) 1902. Price to non-members 1 guinea.

THE New Sydenham Society has done much useful work. It has issued an excellent Atlas of the Diseases of the Skin and also one on Pathology and a valuable Lexicon of Medical Terms, in addition to a very large number of translations of important foreign works on medicine. It has now commenced a very great undertaking: it intends to issue a large atlas containing illustrations of disease as seen in the living patient and this will, it is hoped, "constitute a guide to diagnosis of great value to the practitioner in all departments of our profession." The double section before us contains illustrations of xanthelasma and xanthoma. The general practitioner may be inclined to ask of what use to him is a series of plates illustrating xanthoma which he is hardly likely ever to see. There may seem at first sight some justification for such a question, but on reflection it will be seen that it is of great importance to be able to recognise xanthoma easily because it is frequently associated with diabetes and it may lead to an examination of the urine when no symptoms point to diabetes. Thus one who could diagnose xanthoma might be able to diagnose diabetes early, while many would fail to detect the diabetes because they had not recognised the xanthoma. We urge all members of the profession to subscribe to this valuable atlas; no one could fail to learn from it, for the eye learns more readily and retains more firmly than the ear. The plates are excellent; 14 of them are in black and white and eight are coloured.

The Chemical Changes and Products resulting from Fermentations. By R. H. ADERS PLIMMER, D.Sc. Lond. London: Longmans, Green, and Co. 1903. Pp. 184. Price 6s.

FERMENTATION has afforded a very interesting theme for study and the subject has developed enormously during the past decade. It means now something more than the mere conversion of sugar into alcohol by means of yeast or yeast metabolic products, yet we may be pardoned for pointing out that the name had its origin in the boiling appearance of grape juice during its conversion into wine. Dr. Plimmer has presented us with an admirable essay which though not voluminous conveniently and accurately summarises our present knowledge of the subject and his book is valuable because it brings into review in relatively small scope the upshot of the numerous researches that have now been made. As fresh discoveries come to light our preconceived ideas have of course to be modified. No better instance of this can be cited than the discovery by Buchner of a soluble ferment or enzyme existing in yeast which can set up alcoholic fermentation in saccharine fluids. The change was previously regarded as solely the result of the life of the yeast cell. We should have thought that Dr. Plimmer would have referred more fully to Buchner's work, whereas in point of fact he makes quite slight references to it. Considering how radically Buchner's work is calculated to alter our views as to fermentative change being produced by the living organism and not by the enzyme which it secretes this aspect of the question might have been dealt with much more fully than has been done. This does not, however, detract from the value of the work as expressing the position clearly and concisely at the present time. Dr. Plimmer sums up this position as follows: (1) That the active agent in all cases is a living organism; (2) that this organism sets up either by its own metabolism or by bodies secreted by, or excreted from, it changes in substances of different constitution—e.g., carbohydrates and albumin; (3) that these changes are principally hydrolytic and that some are oxidative and a few are reductive; (4) that the results of these changes are generally simplifications of the original body; and (5) that in certain cases synthesis occurs. At the end of the volume there is an excellent bibliography as well as a complete index of authors.

LIBRARY TABLE.

The Building of the Body. By ALBERT BROADBENT. Manchester: Albert Broadbent. 1903 Pp 119. Price 2s. 6d. —This little book, which purports to deal with "the development of health and strength and prevention of disease by wisely selected food," begins with a completely unnecessary marshalling of evidence to prove that the food of a nation is important to the nation. It goes on to give specimen diets, of which three-quarters are vegetarian and all are faddy, and closes with a note of personal experience, a eulogy of nuts as food, and a string of figures purporting to show the chemical composition and nutritive value of food. Mr. Broadbent, it appears, suffered for ten years from biliousness, "so much eventually that his friends said he had cancer of the stomach." Some months ago, he informs us, he added to a diet "largely makeshift—white bread, potatoes, and a little butter"—a fourth meal "of not more than four or five ounces bread and butter and a simple beverage eaten immediately before retiring." Apparently—we say apparently, for Mr. Broadbent is not a pellucid writer—his symptoms of cancer have abated and the "dandruff which he had has vanished." It would be easy to quote from this book passages to show that Mr. Broadbent has no particular qualifications or knowledge justifying him to aspire to instruct the public on such a topic as the prevention of disease by diet.

The Dentists Register. London: Spottiswoode and Co. 1903 Price 3*s.* 4*d.*—The Dentists Register for 1903 shows that the names of 4617 dentists now appear on the official roll. Of these 2106 hold qualifications from the different corporations—viz., from the Royal College of Surgeons of England (1243), the Royal College of Surgeons in Ireland (421), the Royal College of Surgeons of Edinburgh (274), and the Faculty of Physicians and Surgeons of Glasgow (168); while 2466 practise upon their declaration that they were in *bonâ-fide* practice of dentistry before July 22nd, 1878. The small residue of names are those of dentists practising in right of medical degrees and diplomas and of dentists with colonial or foreign degrees. It will be seen that the number of dentists practising upon diplomas obtained by examination now amounts to over 45 per cent. of the total number of the roll.

Health and Home Nursing. By FLORENCE L. MATHER. London: James Clarke and Co. 1903. Pp. 122. Price 1*s.*—The articles of which this book is composed have appeared in serial form in the *Newcastle Weekly Chronicle.* We can understand that for publication in such form they were very well fitted, and on the whole we think that they are worth re-issue in a volume, for although their information is very elementary and is contained in books already published, still it is put in an extremely clear and readable manner, while the large extent of ground indicated by the title is covered as far as essentials are concerned.

An English Handbook to the Paris Medical School. By A. A. WARDEN, Visiting Physician to the Hertford British Hospital, Paris. London: J. and A. Churchill. 1903. Pp. 74. Price 2*s.*—The design of this little book is to enable the *étranger* to find at once the post-graduate or special medical work that he has come to Paris to pursue, and as it is written on a very comprehensible and orderly plan it should prove very useful. All the more important hospitals of Paris are set out, the names of the medical staffs are given, together with their special subjects, and the hours when they operate or lecture. A daily diary is compiled for the post-graduate student from this information, while information is added about various museums and libraries. Lord Lister and Professor W. W. Keen testify in prefatory letters to their belief that Dr. Warden's little book is wanted and we agree with them. The information is often asked for and it has never been available before.

The Indian Medical Service, Past and Present. By Surgeon-General W. B. BEATSON, M.D. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1903 Pp. 59—Surgeon-General Beatson, late Deputy-Surgeon-General of the Lahore Division, has republished in book form an interesting article upon his distinguished service which appeared last year in the *Imperial and Asiatic Quarterly Review.* He tells the story of the early ships and chirurgeons of the East India Company and shows the value of the services rendered by Gabriel Broughton, surgeon of the ship *Hopewell*, to his country when he asked as a reward for his medical and diplomatic services at the Moghul Court liberty for the English to trade free of duty with Bengal. Broughton's talents and self-sacrificing zeal must always be regarded as having laid an essential part of the foundation of our Indian Empire. Other famous members of the Indian Medical Service whose exploits are narrated in full are J. Z. Holwell, the historian of the "Black Hole," and Surgeon Fullerton, the survivor of the Taka massacre. Surgeon-General Beatson's pamphlet ends with a comparison of the present and past position of the officers in the Indian Medical Service in which he speaks words of unstinted praise of the service as "the best paid and best pensioned medical service in the empire." We refer our readers to our report of the annual dinner of the Indian Medical Service[1] for obvious evidence that the whole service does not share Surgeon-General Beatson's rosy view.

Le Traitement de la Constipation. Par Dr. FROUSSARD. Paris: J. B. Baillière et Fils. 1903. Pp. 95. Price 1 fr. 50 c.—In this little book the author has summarised modern knowledge of a common symptom in various pathological conditions with considerable shrewdness and neatness; but it is difficult to see how such a subject as constipation can be advantageously considered by a medical man as a separate entity having even the most general rules of treatment, local or hygienic. The public, at whom Dr. Froussard's lessons may be aimed, can learn both from the author and from a preface supplied by Dr. Maurice Soupault that indiscriminate self-drugging with purgatives is useless and dangerous.

The Mother's Guide to the Care of Children in Sickness and Health.—By Dr. LYDIA LENEY. London: C. Arthur Pearson, Limited. 1903. Pp. 253. Price 3*s.* 6*d.*—Dr. Lydia Leney is well qualified by her appointments to write a small book to be of use to mothers who living in rural districts or sparsely populated colonies need a practical guide to which they can refer in cases of illness or accident until medical aid can be obtained. Of course, when a practitioner takes upon herself or himself the responsibility of giving advice to laymen the difficulty must be faced of how much to tell. Now in spite of the simplicity of Dr. Leney's language and the absence of pathological theorising, a considerable amount of medical knowledge is, to our mind, often required to follow her teaching. This may lead to difficulty.

JOURNALS AND MAGAZINES.

International Clinics. A Quarterly of Illustrated Clinical Lectures and specially prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pædiatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose, and Throat, and other topics of interest to students and practitioners. By leading members of the medical profession throughout the world. Edited by HENRY W. CATTELL, A.M., M.D., Philadelphia, U.S.A. Vol. III., Twelfth Series, 1902, pp. 306; Vol. IV., Twelfth Series, 1903, pp. 312. London: J. B. Lippincott Company. Price 10*s.* 6*d.* per volume.—This interesting quarterly is hardly as well known in this country as it deserves to be. Each year four volumes are published and each volume contains a large number (from 25 to 30) of clinical lectures on important subjects delivered by well-known hospital surgeons, not only of the United States of America but also of many other parts of the world. For instance, in one of the volumes under review there are a lecture on the Treatment of Urticaria by Professor Hallopeau of Paris; one on

---

[1] THE LANCET, June 20th, 1903, p. 1761.

Surgical Intervention in Gastric Dilatation, by Professor A. Cardarelli of Naples; and one on the Treatment of Face Presentations, by Dr. Robert Jardine of Glasgow. In addition one or two other articles are added; we may specially mention a useful article on the Blood in Health and Disease by Dr. Thomas S. Brown of the Johns Hopkins Medical School; this occupies nearly 100 pages and reviews all the recent work on the changes in the blood in disease. We think that there is no more pleasant way of keeping in touch with the latest developments in medicine than by subscribing to, and reading, this quarterly.

The Cornhill Magazine.—This magazine continues its series of articles upon Prospects in the Professions. In the June number "Medicine" is considered. The writer of this contribution has a thorough grasp of the whole subject and although no name is given it is evident that he must himself be a member of the profession about which he writes. A large amount of useful information is afforded. The actual selection of a school is quite rightly not touched upon, but for the benefit of those who are not acquainted with the internal working of such an institution it is pointed out that a medical school in the present day is a very serious and highly organised academic institution, spending vast sums on its museums, laboratories, and class rooms, and carrying on its work by the help of a large staff of lecturers, demonstrators, tutors, and clerical teachers. The intending student is warned as to what is before him by the words, "The modern student, if he wishes to qualify at all, is one of the hardest worked young men to be found. ...... A modern medical school is no place for an idler, and idlers are sooner or later requested by the authorities to 'move on.'" Very excellent remarks are also made as to the courses which may be pursued when all the examinations have been successfully passed. The young practitioner may embark in general practice, he may enter one of the public services, or he may qualify himself for "consulting work." The pages devoted to this article will well repay perusal. When a young medical man has just become qualified, it is often a very difficult matter for him to decide as to what he shall do next. Unless he can take the advice of a relative or friend well posted in such matters, he may adopt a branch of the profession for which he is entirely unfitted. In the article now under consideration the whole matter is briefly but ably set forth, and it may well be consulted by those who are not sufficiently informed on medical matters to enable them to arrive at a decision as to the course of professional life that they should enter on.

THE ETIOLOGY OF LEPROSY.[1]

AT a meeting of the Bombay Medical and Physical Society held on March 20th a discussion, introduced by Mr. Jonathan Hutchinson, F.R.S., took place on the Etiology of Leprosy.

Mr. HUTCHINSON said he was there as a representative and advocate of a theory that the true explanation of the cause of leprosy would be found in connexion primarily with a fish diet. He cited the circumstance that in South Africa leprosy was a new disease and that there was no leprosy at the Cape till the Dutch farmers brought large numbers of Hottentots to work on their farms. The Hottentots never ate fish and never had leprosy before, but the Dutch were obliged to feed them on large quantities of dried fish. The speaker then proceeded to argue that leprosy was not spread in South Africa by contagion. He was of opinion that the only way in which the living bacillus could be received into the system was by the stomach and that such communication took place when food was eaten which had been contaminated by discharges from a leper's hands. It was known that in India lepers sold sweetmeats and fruits and it could be conceived that children might be tempted to buy such articles contaminated as they might be with the discharges of the sellers. This was a way in which they could account for the occurrence of leprosy in a certain number of lepers in India. His suspicion was that in leprosy they had only a form of tuberculosis. Although he fully admitted that leprosy was communicable by food he was prepared to deny that the disease could maintain itself in any non-fish-eating community. Mr. Hutchinson next took up the question of the transmission of leprosy by heredity and maintained that the transference by inheritance or by touch was quite out of the question. He believed that the spread of the disease in the Middle Ages was due to the influence of the Roman Catholic religion which enjoined fish fasts in Lent. A glance at his "leprosy globe" would show that over the whole world the regional prevalence of leprosy was chiefly on the sea coast, on islands, or in river valleys. The results of his tour in India had satisfied him that the fish theory was now better understood in India than before.

Mr. ARTHUR POWELL said that leprosy belonged to a group of diseases known as the infective granulomata and pathological analogy supported the belief that leprosy was no exception to the laws of its group of diseases, but was an inoculable and contagious disease. He remarked that Mr. Hutchinson admitted that the bacillus of Hansen was the direct cause of leprosy, but wished it to be believed that practically the only way that it was taken into man's system was by the consumption of badly cured fish. He pointed out that numerous attempts had been made to grow the lepra bacillus on media prepared from fish in many ways and all with the same negative result. He said that in South Africa the introduction of the disease was more likely to be due to contact with the Malay fishermen, among whom the disease was prevalent, than to a *de novo* growth of bacilli from eating fish, and he quoted the case of New Caledonia where at the time of his birth leprosy was unknown and the people had always eaten fish. A Chinese leper came there who introduced no variation in the fish-eating habits, but leprosy quickly spread. Mr. Powell was of opinion that Mr. Hutchinson had wholly failed to prove his theory. He was loth that any theory should blind the people of India to three known facts: (1) that leprosy was believed by all competent authorities to be due to a specific bacillus; (2) that the bacillus had never been found anywhere except on the person or in the discharges of a leper; and (3) that no authentic case of leprosy had ever been known to arise where contact with a leper or his discharges was not possible.

Mr. N. N. KATRAK said that judging from the experience of other diseases a bacillus alone was not sufficient to account for the production of this disease. A predisposition of the constitution was also an important factor and it was possible that fish-diet might be one of the causes that predisposed the human body to develop leprosy. He hesitated to accept the view that fish-diet was the only or chief cause. Want of sanitary measures, ignorance, and poverty contributed to the spread and continuance of diseases like leprosy.

Mr. HUTCHINSON, in reply, stated that he could not accept the suggestion of the last speaker that leprosy was due to general poverty or unhygienic conditions. He believed that one of the causes of the disappearance of leprosy from Northern Europe was the greater pains taken in the curing of fish and the better quality of the salt used. In reply to [illegible]

therefore be infectious. This was reasoning in a very vicious circle. Mr. Powell was a contagionist, but he must controvert the facts which seem to show that leprosy was [illegible] South Africa were as [illegible] of *de novo* [illegible]

In proposing a vote of thanks to Mr Hutchinson the Hon. Sir B. KRISHNA said that now that Lord Curzon's Government had reduced the salt duty by eight annas he hoped that pure salt would be used in the curing of fish and thus a source of danger would be removed.

---

[1] Transactions of the Bombay Medical and Physical Society, vol. vii., No. 2, March, 1903.

was brought, were vaccinated. Her vaccination followed the usual course and the fact that it had taken place was discovered by her parents on her discharge from the hospital which took place on April 17th, when the action was started.

At the hearing of the action at the county court the evidence on behalf of the defendant was put before the judge with considerable force and clearness. It was pointed out that to have communicated with the parents of all the children, drawn as they were from a large district, would have caused so much delay that it would have diminished or nullified the protection obtainable from prompt vaccination; that to have allowed the wishes of objecting parents to prevail would have necessitated the isolation of their unvaccinated children or the sending of them home to carry scarlet fever or small-pox, or both, to their neighbours; and that the isolation in order to be complete would necessitate a separate room for each child together with the isolation of those attending upon her. Dr. E. W. Hope, medical officer of health of Liverpool, added his evidence to that of the defendant. His long experience and ample qualification to speak with authority gave weight to his words when he informed the court that in his opinion Dr. Brindley had only one course open to him in the circumstances, and that was to extend the known protective measures to all the persons in the ward who had been exposed to infection. He believed that the delay of one day, necessary to communicate with the parents, would have involved the lives of several of the children, and in reply to a question from Judge Bradbury, answered, "I should say there was not one hour to lose. If Dr. Brindley had not taken the steps he did he would have been guilty of negligence." The assent of our readers will be accorded without question to these propositions, but we call attention to them as illustrating the evidence necessary to be given in such cases. A judge and jury have to base their decisions upon evidence, and unimpeachable testimony strictly bearing upon the issues raised, given with as little ambiguity as possible, will always command the attention due to it. In the case at Bury the judge had at an early stage pointed out that although the certificate of conscientious objections obtained by the father in respect of the child exempted him from penalties for not having his child vaccinated it did not in any way forbid the vaccination or render it unlawful. His Honour further pertinently observed that as the child had been vaccinated and was none the worse for it the father's "conscientious belief that vaccination would be prejudicial to the health of the child" would appear to have been without foundation. In deciding in favour of the defendant, he held that although the act of vaccination against the wishes of the parents might be an assault if performed without cause such as existed in the case before him, nevertheless Dr. Brindley had to determine to the best of his judgment what was the proper course to follow, and in doing that he had to take into consideration all the circumstances. The whole case, in short, depended upon whether in the circumstances considered as a whole, it was reasonably right, having regard to the imminent danger, to vaccinate without communicating with the parents or taking any other steps preliminary to action.

It was, of course, beyond dispute throughout that Dr. Brindley had acted with the sole object of protecting to the best of his ability both the child vaccinated and the other children under his charge. He is to be congratulated warmly upon having so far established his position, and any appeal raised upon the question of law will be watched with considerable interest by the medical profession. It may also be suggested that principles are involved in a case of this kind which should affect the actions of physicians and surgeons in many emergencies. A child, for example, may be brought into a hospital suffering from the result of an accident and an operation considered to be necessary may be performed at once. The parents may hold, from religious or other motives, views hostile to all interference with injury or disease. It would be a serious matter, if on the recovery of the child, an action for assault could be brought, not on account of any injury sustained, but on account of a right claimed by the parents to have their permission obtained as a preliminary to anything done on behalf of their offspring. The strict limits of "technical assaults" in cases where medical practitioners cannot quickly get the consent of a person capable of consenting might be laid down by a court of appeal to the advantage and instruction of all, but until this is done the principles enunciated by the county court judge at Bury will appear to reasonable persons to be consistent with justice and good sense.

◆

The Traffic in Diseased Meat.

It seems to be a law governing procedure in public health administration in this country that before reform can be brought about there must be very serious danger, or even death. It is often to no purpose that a Royal Commission sits for many years, cross-examines experts, visits foreign countries, and finally delivers itself of a report, or series of reports, concluding with recommendations aimed at a better state of affairs. Unless the public conscience is very acutely awakened, and the pressure upon Parliament is such that resistance is obviously undesirable in a political sense, these recommendations are liable to become little better than a series of pious opinions. The second Royal Commission on the Control of Tuberculosis made certain suggestions with regard to the qualifications of meat inspectors. The commissioners, in effect, expressed the opinion that those whose duty it was to protect the public against the consumption of diseased meat might be reasonably expected to possess knowledge superior to that possessed by a plumber, a carpenter, or even a butcher. But recommendations and suggestions notwithstanding, the meat inspection of this country is far from being on a satisfactory footing, and the county borough of Hull has recently afforded an instructive example of the conditions under which the meat traffic of a large city may be carried on.

It appears that certain outbreaks of anthrax occurred in farms in the East Riding of Yorkshire and the cases were not in every instance duly notified to the authorities. Moreover, certain of the carcasses found their way to Hull and were there overlooked by the meat inspectors. Much local excitement was occasioned thereby and a special committee of the corporation was appointed to investigate the matter. Fortunately the committee included among its members several medical men and in consequence of this the inquiries were of a searching character. As to the meat inspectors, investigation showed that they were not familiar with the pathological appearances of anthrax. But this lack of expert knowledge is probably shared by a very large number of meat inspectors throughout the country and perhaps this aspect of the inquiry was quite sufficiently pressed by the committee. The most interesting and striking fact that the inquiry elicited was that a large number of carcasses of cattle which have died from disease, or been killed because diseased, find their way from the surrounding country into Hull where the numerous distributing centres and private slaughter-houses render a proper control of such carcasses a difficult matter. It seems that these carcasses are not sold in the country districts because the history of the cattle is too well known, and hence there has arisen a race of what are called "carrion butchers" who after dressing the carcass and destroying, if necessary, the offal, consign it to Hull. The understanding seems to be that if the carcass passes the meat inspector the owner receives payment, while if the carcass is seized no opposition is offered and no money is forthcoming. There is a remarkably law-abiding attitude about these "carrion" butchers or dealers and their non-resistant pose is admirably calculated to aid the end which they have in view. In one case the evidence points to the conclusion that a healthy spleen was substituted for that which properly belonged to the carcass. All these devices are doubtless well known and practised in the "carrion" trade; indeed, we once heard of a suspicious-looking funeral procession being stopped at the confines of a large Irish city when the hearse, which was followed by mourners, was found to contain the carcass of a cow which had died, or which, as the phrase goes, "had been killed to save its life."

The Hull meat inspectors have undoubtedly been slack in prosecuting inquiries as to the origin and history of carcasses brought into the city, and reform is obviously called for. But the circumstances revealed at Hull are but part and parcel of the important problem of a better supervision of our foodstuffs, not only in urban but also in rural districts. This importation of diseased meat from rural into urban districts should be dealt with by proper coöperation between the two authorities or better still by some larger authority, such as the county council, which will be able to inform itself of the movements of diseased cattle and of suspicious carcasses. The committee of the Hull corporation has made certain recommendations such as the appointment of a chief meat inspector who shall also be a bacteriologist. This is a sound recommendation, but we trust that in appointing a bacteriologist it will also be seen that he possesses a sound pathological knowledge and is not unmindful of the tricks of the trade. The committee also advises that carcasses of meat intended to be sold to retailers should be taken to a separate depôt for inspection, that all condemned meat should be sent to the destructor instead of to the manure works, and that when an inspector seizes the carcass of an animal which has been affected with any communicable disease he shall notify the superintendent of police of the district from which the animal has come. We must confess that in addition to this excellent advice we should have been glad had the committee seen its way to recommend that an abattoir fitted with all modern appliances and means for refrigeration should be erected in Hull. A town with a quarter of a million inhabitants might well set the example. So long as animals are slaughtered behind a shop or in private slaughterhouses there will be no reform in England such as that which took place in Germany many years ago and we still hope that Hull, instead of adopting a more or less stop-gap policy, will undertake a thorough scheme. Possibly the committee was depressed by the returns which it received from other large towns in most of which there still remains much to be done. But Hull can well afford to lead rather than to follow and the medical men in the corporation should see that the opportunity is not lost.

Annotations.

"Ne quid nimis."

THE BALLACHULISH CASE.

JUDGMENT was delivered in the Court of Session, Edinburgh, on June 19th in an appeal against a decision of Lord Kyllachy, granting the Ballachulish Slate Quarries Company, Limited, interdict against Dr. Lachlan Grant, West Larroch, Ballachulish, from carrying on his practice as representing them in Ballachulish. Dr. Grant was in 1900 appointed medical officer to the employés of the quarry, a certain sum being deducted from the wages of the men each week for fees to the defendant. The Lord Justice Clerk, giving the leading opinion, said: "At first sight this case presents a very narrow aspect but on minute examination of the merits and elements I can only come to one conclusion. The defendant was engaged by the Quarries Company, and by them only, to act as medical adviser to their employés. Being engaged by plaintiffs, who else was to dismiss him, even granting that his salary was made up of weekly deductions from the men's wages? Of course, I quite recognise that had the employés had a voice in the selection of the physician another light would have been thrown on the case, but this was not so, and taking everything as it stands I am of opinion that the decision of the Lord Ordinary was a perfectly correct one and think that it should be upheld." Lord Young said: "I am of opinion that defendant is entitled to *absolvitor* in respect that the plaintiffs in dismissing him signified that they no longer gave him their authority to act as medical man to their employés and that so far as they were concerned he was to act no more after a certain date. On this becoming public the workmen held a meeting which was attended by landed proprietors and other influential persons in the district. At that meeting it was unanimously agreed that defendant ought to be kept on. Plaintiffs, however, paid no attention to this and persisted in their determination to dismiss Dr. Grant. Now who were the best judges of the competency of defendant? Who had the best right to move for the dismissal or retention of the defendant? The workmen whose contributions were going to make up defendant's salary and who, along with their families, were being attended by defendant, or plaintiffs who were acting as agents through whom defendant was engaged? Then one had to take into consideration the number of workmen employed. There were, it was said, over [illegible] men employed in the quarry and surely the desire of [illegible] men ought at least to have been heard. On the [illegible] matter I think this interdict ought to be dismissed."

Most of the cells had disappeared without leaving any trace of their existence; the remaining cells showed pigmentary degeneration and confluence of the Nissl's bodies into a homogeneous mass. The tracts of degeneration became more superficial as they were traced downwards through the dorsal and into the lumbar segments of the cord. The pathological changes are summarised as comprising, first, a uniform disappearance of the motor cells in the spinal cord and especially in the cervical and lumbar enlargements; secondly, a degeneration of a zone of nerve fibres in the antero-lateral region skirting the cornua in the cervical region; thirdly, a proliferation of neuroglia in the degenerate areas of white matter and within the anterior cornua, the proliferation being denser in the cervical than in the lumbar region; fourthly, atrophy of the anterior spinal nerve roots; and, fifthly, relative integrity of the crossed and direct pyramidal tracts in the cord. The lesion is apparently a primary atrophy of the anterior cornual cells comparable to progressive muscular atrophy, with the addition that commissural fibres passing longitudinally as well as transversely in the spinal cord from segment to segment are also affected, thus producing the tract or zone of degeneration referred to above. The pyramidal tracts are affected late in the course of the disease and only to a slight extent. This view of the pathogenesis of amyotrophic lateral sclerosis suffices, adds Professor Collins, to harmonise the various observations of Charcot, Leyden, Déjerine, Gowers, and Dana. The cerebral cortex is not affected except very late when there occur symptoms of dementia, such as depression of spirits, meaningless laughter and weeping, and suicidal impulses. All of these symptoms were present in the above case. "The point to be emphasised," adds Professor Collins, "is that mental symptoms occur with considerable frequency in this disease and rarely in progressive muscular atrophy." The etiology of amyotrophic lateral sclerosis still remains obscure. A study of the 104 cases—viz., 94 typical cases collected from medical literature and 10 personally observed—gives the sexes in the proportion of 55 males to 49 females. 30 patients were between 30 and 40 years of age, 29 between 40 and 50 years, and 28 were between 50 and 60 years. The average duration of the disease was slightly over two years, the majority of cases running a course of from one to five years. Probably we must look to pathological chemistry, concludes Professor Collins, for the discovery of the real morbific agency.

STREET COLLECTIONS.

THE amiable ladies and enterprising hospital secretaries whose enthusiasm in the cause of charity takes the direction of rattling, or of instigating others to rattle, money-boxes in the street are probably not aware that the proceeding brings them within the letter of the Vagrancy Act, 1824, and renders them liable to a penalty calculated to have a distinctly discouraging effect upon their zeal. By Section 3 of the Act it is provided that "every person wandering abroad or placing himself or herself in any public place, street, highway, court, or passage to beg or gather alms, or causing or procuring or encouraging any child or children so to do, shall be deemed an idle and disorderly person within the true intent and meaning of this Act." The punishment regarded by our legislators as appropriate to the offence is imprisonment with hard labour for not more than one month. It is, however, not practicable to deal with the matter quite in this spirit and although the passer-by may have resented being badgered by a ragged youth whose *bona fides* could not be regarded as sufficiently established by the printed label on the box thrust in his face, it has hitherto been the lesser evil to abstain from reprisals. In order to supply a more satisfactory means of protecting the public Mr. Akers-Douglas has introduced a Bill to regulate street-begging for charitable purposes. This end is to be achieved by extending the powers given under Section 11 of the Metropolitan Streets Act, 1867, to the Commissioner of Police or to the Commissioner of City Police acting with the consent of the court of mayor and aldermen. With the approval of "one of His Majesty's principal Secretaries of State" either of these authorities will be enabled to make regulations "to be observed by all persons within the general limits" of the Act of 1867 "with respect to the places where, and the conditions under which, persons may collect money in any street for charitable or other purposes." The "general limits" here referred to comprise the region included in a circle of four miles' radius the centre of which is at Charing Cross. The Bill is no doubt aimed mainly at the demonstrations by the unemployed which have been something of a nuisance this year, but it will serve to check also the abuse of charity which is too frequently committed, professedly in the name of certain hospitals.

THE RELATION OF CHRONIC ENGLARGEMENT OF THE SPLEEN TO ANÆMIA IN INFANCY.

THE *Boston Medical and Surgical Journal* of May 28th contains an important article on the Relation of Chronic Enlargement of the Spleen to Anæmia in Infancy by Dr. John L. Morse. The blood of infants under the age of two years differs from that of adults. The amount of hæmoglobin, though high for a short time after birth, is low afterwards. The number of leucocytes per cubic millimetre is greater than in adults, averaging from 10,000 to 14,000. The percentages of the various forms are as follows: small mononuclears, from 50 to 70; large mononuclears, from 5 to 15; polynuclear neutrophiles, from 30 to 40; and eosinophiles, from 1 to 10. Thus the proportion of mononuclears is about thrice that of adults and of polynuclears only about one-half. All pathological changes in the blood are exaggerated in infancy. Dr. Morse gives notes of 22 cases of chronic enlargement of the spleen in infancy in which complete examinations of the blood were made. Rickets was present in all but two cases. The splenic enlargement and blood changes were considerable in two of the three cases in which the rachitic changes were most marked, but were no greater than in other cases in which the latter were slight. Gastro-intestinal disorders were present in every case in which data were obtained. Syphilis was present in two cases. In six cases the liver was enlarged. In general the largest livers were associated with the largest spleens, but in three cases in which the spleen reached the anterior superior spine the liver was not enlarged. There was general enlargement of the lymphatic glands in every case in which their condition was noted. The greatest enlargement was found in cases in which the spleen was much enlarged, but the glands were only slightly enlarged in three out of the four cases of the largest spleens. The number of erythrocytes bore no constant relation to the size of the spleen. In the two cases in which the number was lowest the splenic enlargement was slight; the highest number (5,800,000) occurred in a case in which the spleen reached to the umbilicus. In five cases there were over 5,000,000 per cubic millimetre and in five others there were over 4,000,000. There was no evident relation between the number of erythrocytes and the size of the liver. The diminution in the amount of hæmoglobin was always relatively greater than that in the number of the corpuscles. However, the hæmoglobin is always relatively low in infancy and a relatively great diminution of its amount is characteristic of the anæmias of that period. There was no leucocytosis in eight cases and four of these were among those in which the spleen was largest. The greatest leucocytosis occurred in a case in which the spleen reached to the umbilicus but in another case in which the spleen reached to the umbilicus there were only 8200 leucocytes. Thus there was no constant relation between the number of leucocytes and the size of the spleen. Similarly there was no constant relation between the size of the lymphatic glands and the number of leucocytes. Dr. Morse concludes that when anæmia, splenic tumour, and enlargement of the liver or lymphatic glands are found associated in infancy they are in no way dependent on each other but the results of a common cause—disturbed nutrition; that the anæmia is secondary; and that there is no justification for placing the cases of anæmia in infancy associated with enlargement of the spleen or liver in a separate class and calling them "splenic anæmia of infancy." Of the 22 cases seven were known to be fatal. In one case death resulted from meningitis. In the six other cases there were no complications; in all of these the blood changes were marked; the spleens were very large in three but comparatively small in the others. Nucleated red corpuscles and megaloblasts were numerous in five and two cases respectively which terminated in recovery, hence these forms of cell are not of so much prognostic importance in infancy as in later life. The prognosis depends more on the condition of the blood than on the size of the spleen. The largest spleen may return to the normal size in a few months.

THE DIAGNOSTIC VALUE AND SIGNIFICANCE OF BABINSKI'S GREAT-TOE REFLEX.

MUCH excellent and valuable work has been done during the past three years in regard to the important sign known as Babinski's great-toe reflex, the frequency of its occurrence, and its diagnostic value in the differentiation of organic and functional nervous affections. Three years ago a leading article on this subject was published in THE LANCET[1] based on the work of Babinski and Collier. Dr. G. Marinesco has published in the *Archives de Neurologie* for June a full summary of his observations on 191 persons—viz., 130 cases of organic disease of the central nervous system, 45 normal adults, and 16 newly born infants—the observations being made carefully and repeatedly in each case so as to obtain trustworthy results. In 100 cases of organic hemiplegia of cerebral origin the Babinski reflex was seen 86 times. 31 cases of paraplegia resulting from various causes were also examined. They included 15 cases of Pott's disease of the spine, four each of traumatism of the spinal cord and syphilitic myelitis, two each of pellagra with and without tabes dorsalis, two of sarcoma of the spinal meninges, and one each of amyotrophic lateral sclerosis and cancer of the vertebral column. Babinski's sign was absent in three of the four traumatic cases and in the one case of cancer of the vertebral column but was present in the remaining 23 out of the 31 cases of paraplegia. In 45 normal individuals the Babinski reflex was altogether absent. Among 16 newly born children it was observed only in a single case. It is the rule, however, adds Dr. Marinesco, if the infant is asleep, to elicit, by plantar stimulation, extension of the toes and especially of the great toe. Hence the diagnostic value of Babinski's reflex in infants lies only in the fact that it is (or is not) obtainable when the child is awake. In progressive compression of the spinal cord the tendon reflexes and ankle clonus are apt to disappear while the Babinski reflex still persists. Dr. Marinesco also adds the interesting observation that in recent hemiplegia the Babinski reflex makes its appearance very shortly after the hemiplegic "stroke," whereas the exaggeration of the knee-jerk, which is due to descending degeneration of the pyramidal tracts, makes its appearance somewhat later. Under chloroform narcosis a Babinski reflex already existent disappears, whereas an exaggerated knee-jerk or an ankle clonus co-existent with the Babinski reflex before anæsthesia still persists when the anæsthesia is complete. The Babinski reflex is thus a sign of greater delicacy and value for purposes of differential diagnosis than are the other symptoms mentioned. Occasionally anomalous reactions of the great toe were met with in chloroform narcosis. The collected observations of Dr. Marinesco lead him to the conclusion that the Babinski reflex is dependent upon a disturbance of function of the pyramidal tracts short of, and not necessarily equivalent to, actual descending degeneration of those tracts.

THE DISTRIBUTION OF PLAGUE.

As regards Cape Colony the acting medical officer of health states that for the week ending May 30th the condition of the various places mentioned below was as follows:—At the quarantine station, Saldanha Bay, 2 Asiatic males remained under treatment in the hospital, both being convalescent. At Port Elizabeth 5 cases of plague were discovered during the week—namely, 1 European male and 1 coloured female on May 24th, 1 coloured male on the 26th, 1 Indian male (found dead) on the 28th, and 1 native male on the 30th. At the Plague Hospital 1 coloured female and 1 native male were discharged recovered during the week, leaving 12 cases under treatment. Plague-infected rats continued to be found in the town. At East London 2 cases of plague were discovered during the week—namely, 1 native male on May 24th and 1 native male (found dead) on the 26th. At the Plague Hospital 6 cases remained under treatment. At King William's Town 5 cases of plague were discovered during the week—namely, 2 European males and one European female on May 24th, 1 native male (found dead near Berlin) on the 29th, and 1 European male on the 30th. At the Plague Hospital 1 Indian male was discharged recovered, leaving 9 cases under treatment. Plague-infected rats continued to be found in the town. Neither at Graaff-Reinet nor at Burghersdorp were there any cases of plague or of plague-infected rats, but the latter continued to be found on the railway premises at Queenstown. As regards Hong-Kong a telegram from Sir Henry A. Blake received at the Colonial Office on June 17th announces 120 cases of plague, 12 of the sufferers being Europeans. 78 deaths occurred from plague during the week ending June 13th. As regards the Mauritius a telegram from the Governor received at the Colonial Office on June 19th states that for the week ending June 18th there were 2 fatal cases of plague.

THE LIMITATIONS OF THE PUBLIC HEALTH ACTS.

IN a leading article in THE LANCET of June 20th, p 1751, we dealt with a case illustrating the difficulties which sanitary authorities have to contend with in the performance of their duties. Two further instances have just occurred which serve to strengthen the demand for more ample legal powers. The first is supplied by the result of the appeal in the case of the Consett Urban District Council *v.* Crawford. In this case a number of members of the council and their officers, while making a tour of inspection of their district, were some of them locked in, and others of them locked out of, a yard by the person whose premises they were examining with a view of learning whether a certain nuisance had been discontinued. Proceedings were therefore taken against the obstructor under Section 306 of the Public Health Act, 1875, but without success and the Court of Appeal upheld the refusal of the magistrates to convict on the ground that the representatives of the council were trespassers. The second case involves a somewhat different point. At the Worship-street court the Finsbury borough council summoned a person named Macey for not having cleared a house let in lodgings in accordance with the by-law relating to such matters. The house was registered under Section 94 of the Public Health (London) Act, 1891, which enacts that "every sanitary authority shall make and enforce such by-laws as are requisite for," among other things, "the cleansing and lime-washing at stated times of the premises," and under this section by-laws in the form approved by the Local Government Board had been made requiring such cleansing to be done in the month of April. Mr. Mead, however, held that the by-law was unreasonable and therefore bad and invalid and he dismissed the summons with costs. His attitude appears to have been determined by the consideration that there are many houses of the class here referred to in Finsbury and that there might consequently be difficulty in getting workmen to carry out the necessary operations. If there be sufficient foundation for this opinion the responsibility lies upon the Local Government Board which may perhaps be persuaded to change its wooden "model" by-law for one with effective machinery.

---

[1] THE LANCET, Sept. 9th, 1899, p. 727.

CANCER OF THE RECTUM AS A COMPLICATION OF PREGNANCY.

THE *Scottish Medical and Surgical Journal* for June contains an important paper by Dr. A. W. Russell on the rare condition of pregnancy complicated by cancer of the rectum. Only about 20 cases appear to have been recorded. Probably the reason of the infrequency is that the period of liability to cancer is later than that of child-bearing. Dr. Russell relates the following case. A woman, aged 27 years, was in her sixth pregnancy. In the second month she complained of slight hæmorrhage and pain on defecation. A "constricting band" was felt in the rectum about two and a half inches from the anus. Two and a half months later the pain and hæmorrhage had increased, the rectum was narrower, and the motions were ribbon-like. A month later Dr. Russell saw her for the first time in consultation. Under anæsthesia a dense mass was felt surrounding the rectum for more than two inches from the anus and so encroaching on the lumen that only a finger could be passed with difficulty. As the chances of the pregnancy reaching the time for Cæsarean section were very small there was little reason to consider the prognosis of operation with regard to the child. Mr. R H. Parry agreed to perform abdominal hysterectomy with a view to relieve pelvic congestion, to avoid further risks, and to inspect the pelvis so as to decide as to the possibility of removing the diseased rectum. The cervix was found to be fully dilated and the membranes to be bulging, showing the imminence of abortion. The posterior vaginal wall was so invaded that the least tension would have torn the cancerous mass. After draining off the liquor amnii Mr. Parry opened the abdomen and removed the uterus. As the broad ligaments and other pelvic structures were invaded he did not attempt to remove the growth but performed left inguinal colotomy. Good recovery followed and within a fortnight the pain was so diminished that the customary dose of morphia was discontinued. From a study of the recorded cases Dr. Russell draws the following conclusions. 1. If cancer of the rectum is discovered early in pregnancy immediate radical operation should be considered 2. In advanced pregnancy with a small circumscribed growth the uterus should be emptied before attempting removal of the growth. 3. In advanced pregnancy with a viable child Cæsarean section and hysterectomy should be performed and, if possible, inguinal colotomy should follow and the diseased rectum should be detached from above so as to allow the operation to be easily completed by the vagina according to the method of Rehn or Liermann. 4. When, on the other hand, the disease is beyond radical treatment the child should be saved by Cæsarean section or hysterectomy with or without colotomy as may be necessary. 5. If the child is dead and the cancer is beyond operation Cæsarean section is still likely to be needed unless labour can be accomplished easily and without undue crushing or laceration by the aid of perforation, embryotomy, or version. 6. With modern improvements in methods of operation better results may be expected than those of allowing labour to take place or inducing it through the natural passages.

CHYLOUS ASCITES.

THE very existence of chylous ascites—that is, the presence of chyle in the peritoneal cavity—has been called in question, but there can be no doubt that the condition, though rare, does exist. Guinochet made some observations on a case in which the ascitic fluid apparently contained chyle. The composition of the fluid was determined by analysis when the patient was on ordinary diet, and then the diet was altered to milk with butter beaten up with it. The fluid was again examined and an increase in the amount of fat was observed, and, moreover, butyrine was found to be present, and as butyrine is not a constituent of normal human fat it may be taken that the fat in the ascitic fluid in this case was derived from a lacteal. Chylous ascites appears to occur from blocking of the thoracic duct, though it has been found after trauma of this vessel. The duct is blocked in two ways; most commonly it is compressed by a malignant growth of the stomach or pancreas, or posterior mediastinum, but a few cases have been recorded in which the obstruction has been at the opening of the thoracic duct at the junction of the left subclavian and internal jugular veins. The abdominal lymphatics become distended and one or more give way, allowing the chyle to escape into the abdominal cavity. As might be expected, when the point of obstruction is high up chyle has also been found in the left pleural cavity, because the left half of the thorax drains into the thoracic duct, while the right half is drained by the right thoracic tract. In the diagnosis of chylous ascites one possible error has to be guarded against. Ascitic fluid may be milky in appearance and yet there may be no admixture of chyle, for a breaking-down carcinoma of the peritoneum may make the fluid milky. Still, as abdominal carcinoma is the commonest cause of true chylous ascites, a microscopic and chemical examination is necessary before the diagnosis can be considered certain. In THE LANCET of June 20th, p. 1740, we published an account of a case of this rare condition which was under the care of Mr. A. H. Burgess of Manchester

URINARY CHANGES AFTER INJURIES TO THE HEAD.

IN an interesting communication to the *Monatsschrift fur Unfallheilkunde und Invalidenwesen*, 1902, Heft 12, Dr Borchard discusses the occurrence of glycosuria, albuminuria, and cylindruria after severe injuries to the head. He investigated the condition of the urine in a number of cases as soon as possible after the injury and found noteworthy changes in two of them which he records. The first case was that of a young labourer, aged 17 years, who fell from the second storey of a building and sustained a fracture of the base of the skull. One and a half hours after the injury the urine was found to contain 1·2 per cent. of albumin, 1·5 per cent. of sugar, numerous red blood corpuscles, and casts. These conditions gradually disappeared and the patient recovered completely, and on testing him for alimentary glycosuria a year later a negative result was obtained. The second case was that of a young man, aged 20 years, who sustained a fracture of the base of his skull from a falling scaffold pole. On his arrival in an unconscious condition at hospital six hours after the injury, his urine contained traces of albumin, 1⅔ per cent. of sugar, but no blood or casts, though granular casts appeared shortly after. The patient died 27½ hours after the injury and at the necropsy no changes in the medulla oblongata were found either on macroscopic or microscopic examination, but there were two small areas of softening in the apex of the temporal lobe and a few small hæmorrhages in the cortex. There was slight cloudiness of the cortical and medullary substance of the kidney. Dr. Borchard further gives a summary of the literature of the subject. According to Higgins and Ogden glycosuria occurs in 9·43 per cent. of injuries to the head and is usually complicated by albuminuria This condition gradually gets less marked and eventually completely disappears in most cases. An alimentary glycosuria or a true diabetes may follow the injury to the head in a certain number of cases and may persist in a few of them, while the occurrence of diabetes insipidus after such injuries is well known. Dr. Borchard attributes the urinary changes to disturbances induced in the circulatory apparatus of the kidney by the cerebral injury, but states that an actual lesion in the region of the fourth ventricle is not an essential in their production.

THE next competition for the Howard Medal of the Royal Statistical Society (1903-04) will take place in the ensuing session. The essays must be sent in on or before June 30th, 1904. In addition to the medal a grant of £20 will be awarded to the writer who may be the successful competitor. The subject is—"The Effect, as shown by Statistics, of British Statutory Regulations directed to the Improvement of the Hygienic Conditions of Industrial Occupations." Any necessary explanations may be obtained at the office of the society, 9, Adelphi-terrace. Strand, London, W.C., by application to the secretary of the society, Mr. Benedict W. Ginsburg.

THE Pathological Society of London will meet at Oxford in the Pathological Laboratory, South Parks-road, on Saturday, July 4th, from 4 to 6 P.M. There is a train from Paddington to Oxford at 1.45 P.M. Dinner will be provided at 6 45 at Magdalen College. Members who propose to dine are requested to give notice to the Regius Professor of Medicine, Oxford, before July 1st. The price of the dinner tickets, including wine, is 7*s*. 6*d*. The return train to London leaves at 9 20 P.M. Communications will be made by Dr. Beddard, Dr. Pembrey, Dr. Spriggs, Dr. Dreyer (Copenhagen), Dr. Haldane, Dr. Ritchie, and Dr. Muir.

THE governors and medical staff of Guy's Hospital are sending out invitations for a garden party to be held at the hospital on Friday, July 3rd, at 3 P M. The laboratories and museums, the College, the Henriette Raphael Nurses' Home, and the wards will be open until 5 30 P.M. The Wills' Library will be declared open by Sir Frederick Wills, M.P., who will also distribute the medals and prizes gained by the successful students of the year. The guests are invited to join with the governors, the members of the staff, and the students in assuming academic costume.

A *matinée* in aid of the building fund of the Queen Alexandra Sanatorium, Davos, was given on June 22nd, at His Majesty's Theatre, London, by permission of Mr. Beerbohm Tree The theatre was very crowded. Many distinguished people generously paid enormously enhanced prices for seats and the entertainment, which was well received, resulted in the realisation of the large sum of over £5000, which must be highly gratifying to all concerned.

THE Congress of the Royal Institute of Public Health will be held at Liverpool from July 15th to 21st inclusive, under the Presidency of the Right Hon. the Earl of Derby. The business of the Congress is divided into seven sections and the honorary general secretary is Dr. E W. Hope, Municipal Offices, Liverpool, to whom all inquiries should be addressed.

AT a meeting of the Obstetrical Society of London to be held at 20, Hanover-square, W., on Wednesday, July 1st, a discussion on Ophthalmia Neonatorum will be opened by Mr. Sydney Stephenson, introduced by Dr. W. S. A. Griffith. The honorary secretaries will be glad to hear from any who, not being Fellows of the society, desire to take part in the discussion.

WE regret to record the death of Miss Isobel S. Bryson, M.B., assistant medical officer of Camberwell Infirmary, who died at Camberwell from acute blood poisoning following upon a wound made during a post-mortem examination. Miss Bryson graduated in medicine at the University of London in 1900.

THE first honorary degrees granted by the University of London were conferred on Wednesday last—"Presentation Day"—by Lord Rosebery, as Chancellor, upon the Prince of Wales, the Princess of Wales, Lord Kelvin, and Lord Lister.

A CONVERSAZIONE will be held at King's College, Strand, London, W.C., on Wednesday, July 1st, from 9 to 11.30 P.M., preceded by a distribution of prizes at 8 P.M. by Sir William Anson, M.P., Warden of All Souls, Oxford.

THE Duke of Fife, the Lord-Lieutenant of the county of London, accompanied by Her Royal Highness Princess Louise, Duchess of Fife, will open the Epileptic Colony at Ewell on Wednesday next, July 1st.

THE annual prize-giving at the London School of Medicine for Women will take place on Friday, July 3rd. The Hon. Sir John A. Cockburn, M.D. Lond., K.C.M.G., will present the prizes.

AT the annual meeting of the Röntgen Society to be held at 20, Hanover-square, on Thursday next, Lord Blythswood will be proposed as President.

THE MALARIAL SEASON OF 1902 IN ITALY.

THE fourth volume of the Transactions of the Society for the Study of Malaria[1] has just been issued. It consists of a series of 39 papers by different members of the society, most of which take the form of reports of epidemics in various parts of Italy or of experimental work undertaken by the society along the lines of railway. One article by Dr. Schoo gives an account of malaria in Holland in 1902. Four of the papers are devoted more particularly to mosquitoes or their larvæ, one to an account of a search after hæmolysin and globulin in malarial blood, and two to the question of the absorption and elimination of quinine. A review by Professor Celli of the work done in regard especially to the epidemiology and prophylaxis of malaria concludes the volume which is further furnished with 13 maps of different malarious towns and districts described in the reports.

At the meeting of the society held on June 4th Professor Celli, by whom the report was presented, gave the following brief summary of the results obtained by the various workers during the past season.

1. *The epidemiology of malaria.*—The malarial season of 1902 was, on the whole, even milder than that of the preceding year, but there were not wanting, as in 1901, several

---

[1] Atti della Società per gli Studi della Malaria, vol. iv., Roma, 1903.

as yet unexplainable exceptions to the general mildness of the epidemics. Taken as a whole, however, the epidemiological researches of the past year confirmed in many respects previous observations in reference to the geographical distribution of the various malarial parasites, to the different epidemic types in the various parts of Italy, and to the course of the several epidemics of benign tertian, malignant tertian, and quartan fever respectively. They also emphasised many doubts which still required to be cleared up. For example, despite all their efforts they still lacked a sure and ready means of diagnosing latent malaria so as to differentiate clearly primary infections from relapses. And there also remained to be more thoroughly elucidated the subject of relapse itself—that fundamental characteristic of malarial fevers—in connexion with the causes which favoured it, to which, besides those already recognised—namely, over-fatigue and rheumatic influences—must now be added deficiency of nourishment on account of which the patient was unable to throw off the disease, and certain morbific agencies such as inoculation by tubercle which might light up afresh a latent malarial fever. It appeared, too, that true epidemics of relapses might develop anywhere during the fever season, giving a benign character to the epidemic in years of mild malaria. In its turn the pre-epidemic recrudescence of relapses was always very evident in benign tertian and quartan, but it was not wanting even in malignant tertian although sometimes, as in Latium, it preceded by only a short interval, or, indeed, almost accompanied, the commencement of the epidemic, perhaps because then also began the season most favourable to the development of the corresponding hæmosporidia in the stomach of the mosquito and also because the period of incubation of that fever was the shortest. The combination of relapses with primary infections gave the different well-known epidemic types as they were met with between the north of Europe and the south of Italy, each type receiving its character chiefly from the predominance of some particular species of parasite. In Italy, however, the course of each of the three epidemics of benign tertian, malignant tertian, and quartan was substantially the same in the different parts of the country. It was also necessary that paludism and the occurrence of the anopheles should be studied more closely and that their relations should be determined with the presence, the disappearance, the spontaneous diminution, the intermittency, and the recrudescence of malaria—in short, with all its autochthonous variations. These were so many biological problems bearing upon epidemiology which still awaited solution. Further, the mutual relations between agriculture and malaria had been investigated during 1902. For example, it was noticed that the connexion between ricefields and malaria was not always and everywhere the same, for whilst the opening of new ricefields was always accompanied by a great extension and increased intensity of malaria the cultivation of the rice, on the other hand, did not interfere with the diminution or even with the disappearance of the epidemic, just as it never interfered with its periodical annual oscillations. Likewise it had now been definitely ascertained that the maceration of hemp and of flax was inimical to the life of the larvæ of anopheles. Finally, it was necessary to define still more clearly the relations between meteorology and malaria, especially between the temperature and the development of the various hæmosporidia in the stomach of the mosquito and between the temperature and the course of the several epidemics of mild tertian, malignant tertian, and quartan respectively. Meanwhile it might be affirmed that these relations could neither be identical nor uniform for the three parasitic species and for the three corresponding epidemics of malaria. In conclusion, there were several epidemiological problems (not, however, affecting the new etiological theory of malaria) upon the solution of which the experience of the past year had thrown no light and which must remain for future investigation.

2. *The prophylaxis of malaria.*—Upon this subject the results obtained were more decisive and more harmonious than those which had been elicited in regard to the epidemiology. First of all, it had been proved experimentally that the absorption of quinine introduced by the mouth in the form of tablets such as those supplied by the Italian Government was effected quite as rapidly and efficaciously as happened when the drug was administered in the form of powder or in solution. It was further demonstrated that the daily exhibition of small doses (from 25 to 50 centigrammes) had the effect of causing an accumulation of the alkaloid in the blood, at the same time obviating rather than producing the phenomena of cinchonism. Again, the clinical observations of all the members who studied the question coincided with experimental results in confirming the therapeutic efficacy of quinine in tablets and in throwing into relief the marvellous power of quinine as an antidote and the absence of any inconvenience attending its administration even when continued for months in generous doses. There was perhaps no other example in pharmacology of an antidote so perfect—that is to say, of one the action of which was so rapidly established and could be so long continued as that of quinine. In addition to this its administration could be interrupted, whenever desired, without any disturbance, whilst the curative effects of larger doses did not suffer any diminution on account of the system being habituated to the smaller ones. This mithridatic property, however, was fully displayed only when the quinine was administered daily, or at most at intervals not greater than three days. Intolerance of the drug was limited to a few individuals. The contributors to the report were unanimous in affirming that there was no better specific against malarial infection, whether preventive or curative, than quinine. Arsenic and iron had no direct curative action in malaria; they might, indeed, have an indirect effect, but whether they were really successful as an adjunct to quinine in preventing relapses could not yet be definitely stated, whereas it was very certain that good nourishment was more effectual than arsenic and iron in the radical cure of latent malaria and in warding off, as far as was possible, the occurrence of relapses. To succeed in this last aim the secret was to give quinine with the utmost assiduity and to continue to give it for a long time after the febrile attacks had been cut short. And if, in spite of the treatment by quinine skilfully administered and if sometimes after intervals of perfect health there should be a return of fever, they must still have recourse to quinine as the most trustworthy remedy. Owing to the resistance of the relapses to quinine it was found, as might be expected, that no notable diminution of the epidemic of malaria followed its use, even in large doses, for the pre-epidemic curative treatment of patients who were actually malarious or about to become so. Fortunately, its prophylactic action was much more ready and efficacious. In doses of two grammes (30 grains) per week for an adult (one half the quantity for children) administered by the continuous or daily method (from 20 to 40 centigrammes per day), or even by the interrupted or weekly method (one gramme per day on Saturday and Sunday), they would certainly succeed in reducing to a minimum the new cases—i.e., those with primary infection—and also in diminishing greatly the number of relapses which were prone to continue to recur with such obstinacy. Of a total of 3055 persons thus prophylactically treated in 1902 only 235, or 7·7 per cent., were affected with primary fevers or with relapses. With a mixed prophylactic treatment by means of quinine, arsenic, and iron, the effects were less successful than with quinine alone, the percentage of attacked under this method being from 14 to 20, whilst with arsenic and iron alone the results were absolutely negative. Thus in any anti-malarial campaign there was *only one* remedy which they could not do without, and that was quinine. It was high time that every medical man in Italy understood this and learned to appreciate the value of the very powerful weapon for combating malaria which was put into his hands by the law for the gratuitous supply of quinine for the benefit of all the working people in malarious localities. The physician should therefore understand thoroughly how to make use of this truly sovereign remedy and accordingly now that the law placed completely at his disposal a supply of quinine for the poor he should leave off the old method of treating the febrile attacks only with a few doses barely sufficient to cut them short and should adopt instead the following rules: (*a*) When other prophylactic measures could not be counted upon it was necessary to give a *preventive* course of quinine to the healthy as well as to those who might have a latent infection. The distribution of quinine on a large scale by the day or by the week was easily effected when saccharated tablets were employed. The cost was trifling—namely, from two to three lire (*1s. 8d. to 2s. 6d.*) a head for a whole season of four months. The quantity of quinine required per head for the whole preventive campaign was less than was often required for cutting short definitely a fever once contracted. (*b*) In the case of those very few individuals who, in spite of

the preventive treatment, contracted fever it was necessary to cut short the attacks with therapeutic doses and to continue these large doses for a long time (from two to four weeks) before recommencing the preventive treatment as before. (c) In the case of those patients who, in spite of the preventive treatment, continued obstinately to get relapses the administration of therapeutic doses (from half a gramme to one gramme) must be prolonged for a long time (from four to six weeks), and so soon as it seemed desirable the tonic remedies arsenic and iron should be added. Thus, from one year to another the sad inheritance of the infected would continue to diminish and with perseverance they might succeed in greatly reducing, and in time in almost wholly annulling, the tribute which the rural population was paying to malaria. It was for medical men to attempt this on a large scale, beginning with a part of the population. The beneficial effects which would accrue would prove the best stimulus for the future to the rest of the population in teaching and persuading them by the eloquence of facts how under the guidance of the medical profession and with the help of their own efforts they could, without expense and with almost no inconvenience, easily preserve their health during the months when, and in the places where, formerly people sickened and died from malaria. For those who were not obliged to work in the open air during the most dangerous hours (dawn, sunset, and night) and who possessed a house or shelter to protect them from the attacks of the pestilent mosquitoes, there was also the system of mechanical prophylaxis, which both in Holland and in Italy continued during 1902 to yield the most brilliant results. It would suffice to quote a few statistics to demonstrate this. The railway company which in 1901 applied the system over 573 kilometres of the most pestiferous parts of their lines, benefiting 4138 persons, extended it in 1902 to about 750 kilometres to the benefit of 5600 persons, among whom in consequence malaria, instead of being the rule as formerly, had now become the exception. The Direction-General of Customs which in 1901 as an experiment protected 20 barracks of its officials against mosquitoes in 1902 protected similarly 72 barracks. The results had been so good that both the administration of the railways and that of the customs had still further extended this system of prophylaxis. For various reasons, however, it was little suited for the circumstances of the peasants, for whom the prophylaxis by quinine was best adapted, but this did not alter the fact that wherever there was a house or shelter which could be protected against the entrance of mosquitoes there malaria ceased to be a domestic epidemic. In fact, amongst a total of 5851 persons to whom they could point as having enjoyed in 1902 the great privilege of this mechanical prophylaxis, there occurred in all only 2·8 per cent. of new or primary infections and only 10·1 per cent. of relapses. The method of prophylaxis by the destruction of the mosquito could not yet succeed in the battle with nature, which provided so prodigally for the reproduction of that insect; it could therefore have nothing more than a local and very limited application. A study had also been made of the place which the new theory of malaria took in relation to the great works for the improvement of the land according to the various systems carried out in different parts of Italy. It was ascertained that every drainage system exercised a distinctly deterrent effect upon mosquito life over the improved area, but the deficiency or neglect of small complementary drainage operations and the want of proper care of the drainage canals often neutralised the effects of the best of these systems. Fortunately even when the drainage itself did not succeed in wholly extirpating the anopheles it was always the first step towards the hygienic improvement of an extensive territory, the second step being the cultivation of the ground without which the expense and labour of drainage were all thrown away.

With the prophylactic measures above mentioned at their disposal they were now in a position to protect both the labourers engaged on the drainage works and the agricultural colonies on the improved areas. To this end the special sanitary legislation against malaria should serve admirably. After the first law of Dec. 23rd, 1900, for the State control of quinine, there was enacted another on Nov. 2nd, 1901, by which quinine might be supplied by the district surgeon gratuitously and plentifully to all labourers and peasants in malarious places at the expense of their employers; and all labourers who depended directly or indirectly upon the State were granted the right of having their habitations protected against malaria at Government expense. All the observations made by their associates in 1902 served to show upon what a solid scientific and experimental basis the laws against malaria had been founded. They might therefore congratulate themselves that, all obstacles having been finally overcome and the malarious zones in many communes of the kingdom having already been marked off, these two beneficent laws will begin during the approaching fever season to render those inestimable benefits which had always been observed to follow them wherever in experimental and mission stations they had been able to apply them. It was now their duty to see that those laws, which had issued through the efforts of the Society for the Study of Malaria, were properly applied. Meanwhile, with the object of educating the people upon the question, 4000 copies of a pamphlet explaining and making known the anti-malarial legislation had [illegible], whilst another pampl[illegible]llations against malaria [illegible]

After having [illegible] society during 1902 in presenting the fourth volume of its studies with its 39 original memoirs richly illustrated Professor Celli concluded his relation with a simple statement of fact—viz., that the whole of that important work was represented in the balance sheet by the small sum of 11,384 lire (£455).

THE ROYAL SOCIETY'S (SECOND) CONVERSAZIONE.

THE second conversazione of the Royal Society was held on June 19th, when, as is usual, ladies graced the occasion, while to some extent the exhibits shown at the first meeting, which was held on May 15th, were repeated. Thus, Sir William Crookes once more demonstrated the properties of the emanations of radium, Dr. W. J. Russell his photographs of dust deposits, Professor F. T. Trouton, F.R.S., his hydrometer and viscosimeter, Sir Oliver Lodge his new coherer, and so forth.

There were, however, some additional exhibits of considerable interest. Mr. Henry Crookes, for example, showed plate cultures of several kinds of bacteria which had been [illegible] h a mica screen. The [illegible] the "electrons" from [illegible] at the organisms were killed in those places where they had been exposed to the action of only ten milligrammes of bromide of radium. On incubation a bare space which was free from bacterial growth was left on the plate opposite the point where the radium had been placed. The organisms so exposed were the bacillus liquifaciens, the bacillus coli communis, and the bacillus prodigiosus. Dr. W. Ramsden showed some very pretty experiments bearing upon the behaviour of surface membranes, bubbles, and emulsions. The experiments shown were intended to illustrate a theory that the persistence of bubbles and emulsions is due mainly to the separation of solid or highly viscous matter at the surfaces concerned. A magnetised needle floating freely on the surface of plain water takes up a north and south position and is at once deflected by another magnet. A similar needle if floated on the surface of a very weak solution of saponine stays in any position and is not deflected by a magnet. That this is due to surface tension only is shown by the fact that if the needle be immersed in the saponine solution it sets north and south and is easily deflected. Moreover, if the needle be floated on saponine solution and the vessel containing it be suspended by a fine piece of gut, so that it be free to move on approaching a magnet the whole system, needle, vessel, and contained fluid twist as if one homogeneous magnetic solid. A bubble of oil if "blown" in saponine solution by means of a current of more saponine solution remains as a spherical bubble. If the saponine solution inside the bubble be withdrawn the oil film slowly contracts, exactly like a soap bubble or an India-rubber film stretched by water and also the film takes the shape of a drop of water, only upside down. Mr. John W. Warman exhibited a model representing the hydraulic organ of the ancients. This instrument was originally invented by Archimedes and the feature of its construction is that the wind pressure is derived from the weight of an annular mass of water instead of from a heavy weight placed on the folded air-bellows as in the case of the modern "pneumatic" organ. A new instrument known as a "turbidimeter" for determining the turbidity of water was shown in accordance with the ingenious design of Mr. C. Anthony. The instrument consists of two parallel tubes, one containing the water to be examined and the other a Nichol prism. The eye-piece contains another Nichol prism. By rotating the eye-piece the illumination of the one field can be varied until it matches the field receiving the light through the standard thickness of water under examination. This apparatus, it seems to us, should be very valuable in the examination of public water-supplies. Professor E. Rutherford and Mr. F. Soddy showed that the radio-active emanations of radium and thorium can be condensed by means of liquid air, volatilisation taking place, however, as soon as the temperature rises. Their actual quantity is infinitesimally small; they are invisible and unweighable but their presence can be detected by the property of radio-activity. Professor J. Sollas, F.R.S., showed an ingenious method for determining the specific gravity of blood, using only a single drop for the purpose. A fluid heavier and another lighter than blood are introduced through a tube, the heavier first, so that the lighter fluid added subsequently floats upon it. Both fluids consist of a mixture of chloroform and benzine; the specific gravity of the heavier fluid is 1·07 and that of the lighter is 1·04. The two fluids mix by diffusion, a column being obtained in which the specific gravity varies continuously. A drop of blood obtained from a pin prick is then added and this sinks in the column till it reaches a level where the specific gravity is identical with its own. By means of glass floats the specific gravity of the drop of blood may be indicated. An interesting illustration of the way in which gun accidents may arise was given by Mr. J. Y. Buchanan, who showed in the first place the effect which was produced by the momentary relief of great pressure upon spheres at great depths under the sea, pointing out that the collapse of the brass tube in the peculiar circumstances of one experiment is the exact counterpart of a mistake unintentionally made by people out shooting, especially in winter. If the muzzle of the gun becomes stopped with a plug of even the lightest snow the gun invariably bursts. Light as the plug of snow is, it requires a definite time for a finite pressure, however great, to expel it. During this short time the tension of the gases liberated from the powder is so great that the barrel is unable to withstand it and bursts. The Cooper-Hewitt mercury vapour lamp attracted very general interest. The light derived from the electric discharges through mercury vapour is entirely devoid of red rays and the eye sustains little fatigue under this form of illumination. Mr. J. Mackenzie Davidson showed a new stereoscopic fluoroscope which beautifully portrays objects in relief in the path of the x rays.

In the meeting room lantern demonstrations were given by Professor E. D. Poulton, F.R.S., and by the Bioscope Company.

MEDICINE AND THE LAW.

Parents and Medical Aid.

THERE are two more or less well-known religious sects in England the members of which profess not to consider it right to obtain medical aid or to apply anything in the nature of scientific remedies when they are ill, and from time to time cases occur in which death and the question of certification call attention to tenets which, to ordinary persons, appear to be extremely foolish as well as dangerous to human life. No adult can be compelled by law to avail himself of the services of a physician or surgeon and consequently it is only when children die that the question arises whether those having the custody of them should be punished. A number of cases have been tried during the past 50 years in which members of the sect known as the Peculiar People have been charged with manslaughter and other offences according to the facts proveable against them, with various results. At one time an Act of Parliament (31 & 32 Vict., Cap. 122, Sec. 37) made it an offence punishable on summary conviction to neglect to provide adequate medical aid for a child whereby his health should be, or should be likely to be, seriously injured and it was held that in a case where death ensued upon such neglect a conviction for manslaughter might take place. The section in question has for some time been repealed and in its place the Prevention of Cruelty to Children Act of 1894 makes it a misdemeanour for any person who has the custody, charge, or care of any child wilfully to neglect such child in a manner likely to cause such child injury to his health, and in a case argued before the Court for the consideration of Crown Cases Reserved the wilful omission to provide medical aid for a child has been held to be neglect within the meaning of this Act, so that on death occurring through such omission the parent or other responsible person may be charged with manslaughter. Persons so charged have sometimes been convicted and sometimes have been acquitted. It is not easy to obtain a conviction, which must to a large extent rest upon medical evidence. A medical witness in such a case has usually not seen the deceased during the progress of the illness or at any time before death, and unless he is prepared to state positively that the neglect to provide medical aid shortened the life of the deceased there is no evidence of manslaughter. Even if a conviction for this serious offence takes place a very light penalty is imposed owing to a natural desire of the judge to be lenient towards misguided persons acting under the influence of honestly held religious beliefs. Punishments thus inflicted have no deterrent effect. The same parents have been known to let child after child die in similar circumstances of neglect and even though the deaths may not be numerous, because the Peculiar People are few, still the fact remains that these preventable deaths take place, while other children suffer unnecessary pain, and to these, if they do not die, no attention as a rule is called. At the present moment there are parents awaiting trial who, according to the evidence laid before the magistrate, did not call in a medical man when their child to their knowledge was suffering from diphtheria. No comment can of course be made on this particular case, in which the charge is not one of manslaughter but of neglect so as to cause unnecessary suffering. The question, however, may well be ventilated apart from any particular instance whether some special means ought not to be provided by law for the compulsory rescue of the sick children of parents whose religious views are opposed to medical interference. Such rescue or removal need not last beyond the child's restoration to health and would be in accordance with the principle that prevention is better than the punitive measures which fail to provide a remedy. It is not at all certain that parents holding views of the nature indicated would regard it as a hardship or as a martyrdom even of the mildest kind that medical aid should be applied to their children by others under the authority of the law. The Peculiar People hold that they would commit sin by acting voluntarily as if they doubted the passage in the Bible responsible for their conduct (St. James v. 14). It has never, however, been shown that their tenets go beyond this or that they would dream of resisting acts which would be done by others without implicating them and without any connivance on their part. Two sects have been mentioned above; the second, known as Christian Scientists, is of a different character. The Peculiar People, founded in 1838 by two men named Bridges and Banyard, have never increased to any considerable extent and are drawn from the humbler classes in London and its neighbourhood, especially in Kent and Essex. The Christian Scientists, whose non-employment of medical aid is apparently based upon denial of the existence of anything so material as disease and death, are of more recent origin, occupy quite a different social position, and are said to be numerous not only in London but also in the provinces. The Christian Scientist, however, does not seem hitherto to have ventured to test the efficacy of the Prevention of Cruelty to Children Act by allowing his children to die without medical aid or else no instance of his doing so has attracted attention in this country. Possibly his faith is of a less established character than that of the Peculiar People or he may think that a judge would not be inclined to treat an educated man as he would a fanatic with less opportunity for the development of his intelligence. In the United States of America, however, the deaths of the children of Christian Scientists without medical aid being sought are not unknown and they may occur at any time in our own country. The matter is not an easy one to deal with as there would be no certainty that the illness of a child among the Peculiar People or Christian Scientists would ever be heard of. Probably, however, neighbours would be ready to give information if to do so was of any practical utility. At present little can be done except in certain cases where removal is necessary for the purpose of isolation. It must be borne in mind that the sects named do not exhaust the numbers of those who, for religious reasons, disapprove of scientific interference and similar sects may be brought into being. Moreover, it is not easy to see why religious motive on the part of our fellow citizens should excuse our practically acquiescing in the pain and death of their children. We should not, presumably, allow members of fanatical sects to flagellate their children, or to starve them, or to make them perform dangerous acts as tests of their childish faith in accordance with the precepts of a religion devised by some one emulous of the success, financial and otherwise, of Mrs. Eddy. If, however, the religious motive prevents us from inflicting a deterrent punishment when the law is broken we might supply ourselves with means for preventing as far as possible the suffering and death of helpless children.

Bogus Degrees

The libel action Garnett *v.* Clarke tried in the King's Bench Division on June 15th and 16th, in which the bogus degrees conferred by "Harriman University," of Tennessee, U.S.A., formed the subject of inquiry, is of considerable interest to the medical profession. It not infrequently happens that a quack summoned under the Medical Act for the use of titles implying registration endeavours to treat the matter as if the offence were a merely technical one and although he cannot allege that he ever possessed qualifications recognised as such in Great Britain, instructs his counsel to urge on his behalf, in mitigation of an inevitable penalty, that he is a graduate of a university abroad holding highly sounding degrees and to be regarded as a person trained to practise medicine, but excluded by professional jealousy from doing so in this country. The University of Harriman appears to exist to some extent as an educational centre—that is to say, there was evidence that some part of the buildings are in use, though dirty and ill-kept, as a school for boys and girls. Moreover, of 26 professors included in the list of its instructors five were actually traceable as existing, one of whom at the time of inquiry occupied the chair of "domestic science" when not putting principle into practice as housekeeper to an oil agent who, with his wife, lived in a portion of the university buildings The university also possesses a chancellor, for he made a personal offer to confer upon Mr. Garnett, the plaintiff in the libel action, the degree of S.T.D., in addition to that of D.D., apparently without extra charge. The letters S.T.D. were explained by Mr. Garnett in the witness-box as standing for *Sacra Theologia Doctoris*, and the erudition of members of the university was further attested by a letter of the obliging chancellor, who wrote: "I have so arranged your name as to cause my books to show that your degree has been earned and it will come *pro merito* and not *pro honoris*." The examination for the degrees thus earned by Mr. Garnett took place at Ocean Grove and at Philadelphia and he admitted that he had never been to Harriman in his life, although he demurred to the suggestion that he had not been within 1000 miles of it The article, moreover, in the *Christian World* which formed the subject of the libel action, disclosed that a recipient of a Harriman B.A. degree had been examined in the house of Mr. Garnett in London and that the papers had been forwarded sealed to Harriman, or at all events to the United States, to be looked over. Mr. Garnett himself seems to have taken the degrees of B.A., M.A., B.D., and D.D, and really at the price a man less easily contented might have had a few more without laying himself open to the charge of extravagance, for matriculation at Harriman costs 10 dollars, the examination such as Mr. Garnett successfully underwent is charged at 30 dollars, and degrees can be had at 10 dollars apiece. No evidence that medical degrees have been conferred at Harriman was given, but the university does not confine itself to theology, for besides the professor of domestic science already mentioned a professor of astronomy was spoken of who, in non-professional moments, practises as a dentist and legal instruction was described as occupying one week in the year. In any case Harriman University does not stand alone. It is merely a striking example of institutions not confined to the United States which exist, but do not flourish, for the dissemination of bogus titles to the deception of the ignorant and unwary. The *Christian World* is to be congratulated upon the full and public exposure which it has brought about.

New Milk Deficient in Fat.

The Divisional Court in a recent case upheld the conviction of a milk-seller, under the Sale of Food and Drugs Act, 1875, for selling (on being asked for new milk by the inspector) a liquid which had been taken directly from the cow and had not been tampered with or adulterated, but which in consequence of the length of time which had elapsed since the cow had last been milked, was deficient in fat to an extent of 30 per cent., the remainder of the fat having been absorbed by the cow during the unduly long interval between the milkings, the offence being that the article was not of the quality demanded of him.

Adulteration.—Sale by a Limited Company.—Previous Knowledge of Purchaser as to Adulteration.

The Divisional Court in a recent case decided (1) that a limited company is a "person" within the meaning of Section 6 of the Sale of Food and Drugs Act, 1875, and therefore could be convicted; and (2) that a sale may be to the prejudice of the purchaser although the purchaser had previous knowledge, not derived from information given by the seller, that the article sold was not of the nature, substance, and quality demanded by him. The test is: Whether the sale would have been to the prejudice of a purchaser who had not that special knowledge.

Accident Insurance.—Was Death caused by Accident or Intervening Cause?

Mr. Justice Wright recently heard the case of Mardorf *v.* Accident Insurance Co., in which the assured person had taken out an accident insurance policy with the condition that it should not apply to "death" caused by, or arising wholly or in part from, any "intervening cause." The assured on July 2nd accidentally inflicted a wound on his leg with his thumb-nail. His leg became inflamed and on July 9th erysipelas had set in. This was followed on July 12th by septicæmia and on July 16th by septic pneumonia, from which complaint he died on July 22nd. It was conceded by the insurance company that the septic germs, the development of which resulted in the man's death, were introduced into his body at the time of the infliction of the wound. Mr. Justice Wright held that the erysipelas, septicæmia, and septic pneumonia were not "intervening causes" within the meaning of the policy but merely different stages in the development of the septic condition which was immediately brought about by the introduction of the poison and that the man's death was directly and solely caused by the accidental injury to his leg.

Vinegar of Squills.—Acetic Acid.—Standard of Quality.—Analyst's Certificate.

In the recent appeal case of Hudson *v.* Bridge the Divisional Court held that the court of summary jurisdiction was wrong in deciding that there was a standard for the quantity of acetic acid which should be present in vinegar of squills. The court was also of opinion that the analyst's certificate should have reported that the article in question was liable to decomposition and as the certificate did not do so it was void under the schedule to the Sale of Food and Drugs Act, 1875, which provides that: "In the case of the certificate regarding milk, butter, *or any article liable to decomposition*, the analyst shall specially report whether any change had taken place in the constitution of the article that would interfere with analysis."

The Power of an Inspector to procure Samples of Milk outside his own District.

The Divisional Court in the recent case of McNair *v.* Cave decided, with some reluctance, that the power conferred upon inspectors under Section 3 of the Sale of Food and Drugs Act Amendment Act, 1879, to procure at the "place of delivery" a sample of milk in course of delivery to the purchaser in pursuance of a contract of sale cannot be exercised by an inspector outside the district for which he is appointed For instance, an inspector for the city of Westminster cannot intercept at St. Pancras milk intended ultimately for a dairyman carrying on business at Westminster.

When is a Home for Epileptics a "Hospital"?

The Divisional Court in the recent case of Ormskirk Union *v.* Chorlton Union decided that an institution having for its object the care and treatment of persons suffering from epilepsy, which was partially supported by endowments and partially by donations and payments made on behalf of the patient, is a hospital within the meaning of Section 1 of the Poor Removal Act, 1846. One of the judges remarked: "In my opinion a hospital is none the less a hospital because some patients may make payments. It would be placing a great burden upon parishes in which institutions such as these are situated if the residence of patients in them were to have the effect of making the parish liable to support them."

Admixture of Arsenic in Beer.—Analyst's Certificate.—Sufficiency of Particulars.

The Divisional Court in the case of Goulder *v.* Rook decided that a certificate of a public analyst which merely states that a sample of beer submitted to him for analysis "contains a serious quantity of arsenic" is insufficient. The certificate should be more explicit and should contain exact details sufficient to enable the magistrate to come to a conclusion.

The Liability of a Surgeon for Lack of Skill and Care.

In the case of Lanphier *v.* Phipos, which was an action against a surgeon for "carelessness, negligence, and unskilfulness," it was said in the judgment: "Every person who enters into a learned profession undertakes to bring to the exercise of it a reasonable degree of skill and care; he does not, if he is an attorney, undertake to gain a cause in all events; nor does a surgeon undertake that he will perform a cure; nor does the latter undertake to use the highest possible degree of skill, as there may be persons of higher education and greater advantages than himself; but he does undertake to bring a fair, reasonable, and competent degree of skill; and in an action against him by a patient the question for the jury is whether the injury complained of must be referred to the want of a proper degree of skill and care in the defendant or not." And in the leading case of Rich *v.* Pierpont it was laid down that to render a medical man liable for negligence or want of due care or skill it is not enough that there has been a less degree of skill than some other medical man might have shown, or a less degree of care than even he himself might have bestowed; nor is it enough that the practitioner himself admitted some degree of want of care; there must be proof that there has been a want of competent and ordinary care and skill, and to such a degree as to have led to a bad result.

Conclusiveness of Certificate of Medical Referee: Workmen's Compensation Act, 1897.

The Court of Session in the case of M'Avan *v.* Boase Spinning Company held that the certificate given by a medical referee under Schedule I. of the Act (stating that a workman who was in receipt of weekly payments under the Act had recovered from the injuries in respect of which the payments were made, and that although he was suffering from partial disability for work such disability was not connected with the injuries, but was "the result of deficient natural vigour of constitution, together with advancing years"), *was conclusive* against any further claim by the workman for compensation under the Act.

ASYLUM REPORTS.

Cumberland and Westmorland Asylum (Annual Report for 1902).—The average number of patients resident during the year was 677, comprising 344 males and 333 females. The admissions during the year amounted to 190—viz., 88 males and 102 females. Of these 142 were first admissions. Dr. W. F. Farquharson, the medical superintendent, states in his report that the number of admissions was considerably above the average of recent years and had only twice been exceeded in the history of the asylum. Of the 190 patients admitted 176 were chargeable to the rates and 14 were private patients. "The admissions include four cases of congenital imbecility, five cases of epilepsy, two cases of general paralysis, 18 patients over 70 years of age, and five cases transferred from other asylums; the great majority of the cases just enumerated were incurable, and the remainder of the admissions included an unusually large proportion of unfavourable cases." In 28 cases the attack of insanity had lasted more than a year before the patient was taken to the asylum. Nearly two-thirds of the patients were admitted in weak health, seven were in a very exhausted and feeble state, and several died shortly after admission. 57 of the patients who were admitted had suicidal tendencies and 21 had actually attempted suicide. A great variety of causes of insanity was assigned for the cases admitted. Conditions affecting the bodily health were responsible for the onset of insanity much more frequently than were mental shocks or business worries. By far the most important of the causes was hereditary predisposition to insanity, which was ascertained in 32 per cent. of the cases, though it probably existed, adds Dr. Farquharson, in a much larger proportion. In 11·5 per of cent. cases alcoholic intemperance was the exciting cause of insanity as compared with 17·7 per cent. of cases in 1901 and 20·3 per cent. in 1900. "It is pleasing to be able to record," adds Dr. Farquharson, "a diminution in the number of cases due to a preventable cause such as alcoholism. It is to be hoped that the new Licensing Act will have a decided influence in reducing drunkenness, and if it has that effect the community will in time reap the benefit in a diminished amount of insanity and crime." The number of patients discharged as recovered during the year amounted to 70, or 10·3 per cent. of the average number resident. The deaths during the year amounted to 61, or 9 per cent. as calculated on the same basis. Of the deaths, three were due to pneumonia, four to general paralysis of the insane, four to pulmonary tuberculosis, seven each to organic brain disease and senile decay, eight to epilepsy, 13 to cardiac disease, and the rest to other causes. A post-mortem examination was made on every patient who died. The general health of the inmates was good and there was an absence of epidemic or zymotic disease during the year.' The Commissioners in Lunacy state in their report that the patients were neatly dressed, that the wards were comfortable and the building in good order, that the food of the patients was satisfactory and evidently relished by them, and that the medical case-books were very satisfactorily kept. The committee of management states in its report that the weekly charge of maintenance was 9*s.* 4*d* per patient and that extensions to the building are proposed to be made at a cost of £37,000.

Leicester Borough Asylum (Annual Report for 1902).—The average number of patients resident during the year was 791, comprising 326 males and 465 females. The admissions during the year amounted to 197—viz., 72 males and 125 females. Of these 164 were first admissions. Dr. J. E. Montague Finch, the medical superintendent, states in his report that of the 740 patients remaining in the asylum at the end of the year 1902 13 men and 15 women were deemed curable. An unusually large number of patients have been actively suicidal during the year and several determined attempts at self-destruction were made. The principal causes of insanity in the admissions were heredity in 34 cases, alcoholic intemperance in 17 cases, domestic trouble and adverse circumstances in 14 cases, and recurrence of a previous attack in 20 cases. The number of patients discharged as recovered during the year amounted to 68, comprising 29 males and 39 females, or 8·6 per cent. of the average number resident. The deaths during the year amounted to 75—viz., 31 males and 44 females, or 9·4 per cent. as calculated on the same basis. Of the deaths three were due to cerebral hæmorrhage, three to pneumonia, five to cerebral softening, seven to cardiac disease, eight to pulmonary tuberculosis, nine to senile decay, 10 to influenza, 16 to general paralysis of the insane, and the rest to other causes. "The death-rate in 1902," adds Dr. Finch, "was somewhat higher than in the previous year, partly in consequence of an outbreak of epidemic influenza from which ten female patients died, and also owing to the very unfavourable state of the bodily health of many of the admissions, no fewer than six patients having died in less than a week after admission ...... Most of these patients had to be carried in when bought here and never left their beds. The number of bedridden and aged patients continue to increase." A considerable number of improvements and alterations have been effected during the year in regard to facilities for escape in case of fire and with reference to increase of water-supply in case of emergency. The Commissioners in Lunacy state in their report that the general condition of the asylum was excellent, that the wards were bright and plentifully supplied with objects of interest, that the dormitories and bedding were in a thoroughly satisfactory condition, that the patients were neatly clad and orderly in behaviour, and that the medical case-books were well kept. The committee of management states in its report that since the date of the previous report extensions and additions have been carried out in the laundry and administrative buildings without exceeding the estimates. "Previous to the disastrous fire at Colney Hatch Asylum there was found to be some danger in the old part of the asylum. ...... This has been remedied and fire-proof doors between the blocks [and wards] are being added. An additional emergency staircase on the female side has also been constructed." The committee has had under consideration the question of a pension scheme for all officers and servants of the asylum and this scheme when adopted by the committee will shortly be submitted to the Leicester borough council for its approval.

ANKYLOSTOMIASIS AMONG MINERS.

AT the Fourteenth International Congress of Miners, which met recently at Brussels, an interesting discussion was held on the spread of Ankylostoma Duodenale among Coal Miners. There were 75 delegates attending this congress representing five different nationalities and 1,271,500 miners. Such a representative gathering should exercise considerable influence, particularly when the demands made are such as meet the claims of humanity and the interests of the community at large. On this occasion the question of the prevention of ankylostomiasis was introduced by the German delegates. They pointed out that the disease had spread far and wide before its particular character was discovered. The patients were treated as suffering from anæmia and some years elapsed before it was ascertained that the symptoms were caused by the presence of a parasite in the intestines. The newspapers representing the interests of the German miners published many articles on the increase of sickness among the men who worked in the coal-pits. They protested that the sanitary measures prescribed by the members of the medical profession and even those decreed by the law were not applied. It was only after some years of such propaganda that the German Government was at last induced to institute an official inquiry and then it was discovered that in the coal-fields of Ruhr alone there were more than 25,000 miners affected. In four mines particularly affected every miner was carefully examined and there it was found that 90 per cent. had eggs of the worm. The disease seems to have been gaining ground in Germany ever since 1896 and [illegible] ding to the official [illegible] miners had been reduced from 45 to 40 years. They explained that their figures were absolutely trustworthy, for the system of obligatory and universal insurance inforced throughout the German Empire rendered it necessary for the State to keep and to publish elaborate statistics. Nevertheless no explanation was given as to what these figures meant. Was it that the average duration of life among the mining population had been reduced from 45 to 40 years, or that the adult male miner, having survived the perils of childhood, was now only able on an average to work for 40 years? whereas before the year 1896 this average was estimated at 45 years. In any case it is obvious that considerable harm has been done. Extractum filicis maris was the only remedy that had proved efficacious, but the cure was as bad as the disease, for it produced great prostration and sometimes blindness ensued.

The Belgian delegates confirmed what the Germans had said. In the Liège coal-fields a case of ankylostomiasis had been reported in 1883 and a death was attributed to this cause in 1884, but nothing was done, no precautionary measures were taken, till the year 1896. The provincial authorities then appointed a medical committee to inquire into the matter and in certain mines it was discovered that the eggs of the worm were present in the fæces of from 70 to 80 per cent. of the miners. This does not mean that they were all ill, for the egg does not always develop into the larva, and it is only when the worm, a thread-like worm, exists in large numbers that the health of the patient is seriously affected. But it seems impossible to deal with the eggs, for they maintain their vitality even when treated with concentrated sulphuric acid. The disease is a local disease. For instance, on the plain of Herve only one case of infection was found as the result of 1600 analyses. But in one other mine in this same district from 60 to 70 per cent. of the miners were infected.

The British delegates were not able to throw any light on the subject, though Mr. Abraham, M.P., did remark that this complaint had occurred among the miners of Cornwall and that the British Government had taken some precautionary measures to prevent the disease from spreading to the coal mines of the country. As to the nature of such precautions there was a common agreement as to what they should be. It seemed generally admitted that this worm was introduced in various coal mines by some Italian labourers who had been engaged on the St. Gothard tunnel works, where the disease was very prevalent. The dejections were the chief source of contamination. The first and most essential precaution was the introduction of portable sanitary pails in all mines and the adoption of rigorous measures to insure that these pails should be used on every occasion. Where the mine was already infected the miners must be careful not to drink any running water but only such water as was brought down from the surface and known to be clean. Before eating the miners should wash their hands and avoid as much as possible touching their mouths with their fingers whilst at work. Also, so as not to take coal-dust, mud, and earth home from the mines, it was suggested that baths should be provided at the pit's brow and that the miner should wash and change his clothes before he went home. There were cases where the disease had spread from the miner to his family and village. The delegates freely admitted that it would be difficult to persuade all the miners to take such precautions and that the spread of the disease was in part due to their own carelessness. But the authorities were also to blame, they were very slow to act. In Germany the Government had frankly confessed that it had not the means of coping with the disease, the necessary measures would cost too much. When, however, there was a proposal to increase the strength of the navy no such arguments were brought forth and yet the strength of the nation primarily depended on the health of the people. The German delegates insisted that it was a short-sighted policy to allow such diseases to spread. In the North of France, a French delegate explained, the disease had occurred in one coal-mine. The best medical authorities were sent there from Paris, the matter was thoroughly investigated, rigorous measures were taken, and the disease was stamped out. Many lives and much money would have been saved and much suffering and distress prevented if the authorities in Germany and Belgium had been as prompt to act as their neighbours of the Pas-de-Calais coalfields.

PROGRAMME OF THE ELEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE Eleventh International Congress of Hygiene and Demography will meet in Brussels from Wednesday, Sept. 2nd, to Tuesday, Sept. 8th, this year. On Tuesday, Sept. 1st, the international committee of the International Association of the Medical Press will likewise meet in Brussels. According to information just obtained in Brussels about 800 members of the Congress of Hygiene have been enrolled and it is not expected that more than from 1200 to 1500 members will attend. This would be only about half the number that were present at the ninth congress which met at Madrid in 1898. The explanation given to account for this difference is that Brussels is so close at hand and so well known. A pretext for a journey to Spain rarely occurs and therefore many more people availed themselves of the opportunity. However this may be, the falling off in the number of attendants is considered as a most fortunate circumstance. These congresses were being killed by their prosperity and the crowds which they gathered together became quite unmanageable. At Brussels it is hoped that there will be no such crush. On the other hand, there is every promise of good work being done from the technical point of view. The executive committee or central bureau is composed exclusively of practitioners in regard to hygiene

In Belgium the public health services are connected with the Ministry of Agriculture, and the president of the executive committee is M. E. Beco, secretary-general of the

Ministry of Agriculture, intrusted with the general direction of public health services, of hygiene of the roads and ways, at Brussels. The vice-presidents are Dr. A. Devaux, inspector-general of the public health services, and M. J. Leclerc, president of the Central Statistical Commission. The secretary-general is the well-known sanitary reformer and faithful attendant at the International Congresses of Hygiene, Dr. Félix Putzeys, professor at the Liège University Faculty of Medicine. His address is No. 1, rue Forgeur, Liège, Belgium. Communications may also be sent to the secretary, Dr. Voituron, Inspecteur au Service de Santé et de l'Hygiène, Ministère de l'Agriculture à Bruxelles.

Apart from this general committee of management there are special committees for each of the two Divisions and the seven sections into which the Congress is divided. The first Division—that of hygiene—has seven sections. The Demographical Division apparently will not this time be subdivided, though at the previous congresses there were generally two sections of demography. As usual, the first section in the Hygiene Division is devoted to bacteriology in its relations to public health. Dr. van Ermengem, of the Ghent University, is president. The secretaries are Dr. Bordet, director of the Bacteriological Institute of Brabant, and Dr. Malvoz, of the Liège University. Eminent authorities of different nationalities have been selected to present reports on various subjects. For instance, Dr. Bordet himself together with Dr. Denys of the Louvain University are assisted by Professor Max Gruber, Professor R. Pfeiffer, and Professor A. Wassermann, of the Universities of Munich. Königsberg, and Berlin respectively; and Dr. Belfandi, director of the Serotherapeutic Institute of Milan, will prepare and present a report on the action and origin of the active substances contained in the preventive and antitoxic serums. Dr. Roux of the Paris Pasteur Institute and Dr. Ehrlich of the Royal Institute of Experimental Therapeutics, Frankfort-on-the-Main, will report on the best methods of measuring the active properties of serums. Nine reporters from nine different nationalities will deal with anti-diphtheritic serum from the prophylactic point of view. Then there will be a report with regard to the unification of the processes for the bacteriological analysis of water.

The second section deals with food questions and the connexion between the science of the chemist and that of the veterinary surgeon in their application to hygiene. This section will unite with the first section to discuss a report on tuberculosis in men and in animals The secretaries of the second section are Dr. Stubbe, inspector of the veterinary services, and Dr. van Dam, food inspector, both at the Ministry of Agriculture, Brussels. There will be reports in this section on all that relates to milk-supply, on the sterilisation of tinned and preserved provisions, on the pasteurisation of milk, &c.

The third section is entitled Sanitary Technology and comprises the sciences of the architect and the engineer as applied to hygiene. M. Hachez, Ingénieur Inspecteur au Service de la Voirie, &c., Ministère de l'Agriculture à Bruxelles, is the secretary. There will be a report on the bacteriological treatment of sewage, and Mr. Gilbert J. Fowler, superintending chemist at the sewage works, Manchester, together with Dr. Rideal, vice-president of the Society of Public Analysts, London, and Dr. Dunbar of Hamburg, M. Launay of Paris, and M. Rolants of Lille, will draw up this document. Then the question of the separate system of drainage will be reported upon, and for this Mr. Roechling, civil engineer, of Leicester, is one of the reporters. The next subject has also two Englishmen among the reporters—namely, Mr. J. Allen Howe, B.Sc., conservator of the Geological Museum of London, and Mr. Horace B. Woodward, F.R.S., of the Geological Survey of England. Their subject is the conditions that should exist when waters from chalk soils have to be utilised for drinking purposes. Mr. Roechling is also to report on the sanitation of public roads and there are to be reports on the heating and ventilation of dwellings.

The fourth section is devoted to industrial and professional hygiene The secretary is M. Joseph Brughmans, factory inspector at the Ministère de l'Industrie et du Travail à Bruxelles. The first question for consideration is that of ankylostomiasis. There are Belgian, French, and two Hungarian reporters on this subject. The second report is on lead poisoning and Dr. T. Oliver of the Durham University, the medical expert attached to the Home Office, is one of the reporters. The physiology of fatigue and consequently the methods that should govern the organisation of various forms of labour is the third subject. Belgian, French, Italian, and German reporters have been appointed. The conditions of the linen factories and of the brush making trades are each the subjects of special reports. On the last-named subject Dr. T. M. Legge of the Home Office, London, is a reporter, while on the linen trade, Mr. E. H. Osborn, His Majesty's inspector of factories, Home Office, London, and Dr. H. S. Purdon of Belfast are reporters. Miss A. M. Anderson, His Majesty's principal lady inspector of factories, Westminster, is one of the reporters on the question of small workshops and home industries.

The fifth section is devoted to the hygiene of travelling or transport. M. Blancquaert, administrator of the Belgian State railways, will preside, and Dr. de Landsheere, Brussels, is the secretary. The means of preventing the spread of infectious diseases among railway servants and the best methods of disinfecting carriages that have served for the transport of passengers, cattle, or merchandise, are among the subjects to be discussed in this section.

The sixth section is somewhat of a mixed section, for it is to deal with administrative hygiene and presumably sanitary legislation with the prophylaxis of transmissible diseases, workmen's dwellings, and the hygiene of childhood. M. van Hulst, pharmacien *attaché à l'Inspection du* Service de Santé, Ministère de l'Agriculture à Bruxelles, is secretary. The first report is on the feeding of infants: Dr. P. Budin of Paris is one of the reporters. The inspection of schools is the next subject and then comes the war against tuberculosis on which Dr. Brouardel and Dr. Arthur Newsholme, medical officer of health of Brighton, are among the reporters. The question of the prevention of the plague has German, French, Dutch, and Hungarian reporters, but there are no Anglo-Indians, though they possess so much practical experience of this disease. Then there is a long list of the various ways in which the public authorities may help to solve the question of the housing of the poor. This, again, is a subject on which a British reporter might have had much to say, but there is no English name on the list

Finally, the seventh section is on colonial hygiene and Dr. Voituron, secretary of the Congress, is also secretary for this section. The diet of Europeans living in hot climates is the first subject on the list and Major Ronald Ross, C.B., Walter Myers Lecturer in the School of Tropical Medicine at Liverpool, is among the reporters. The prophylaxis of the sleeping sickness, that of beri-beri, and that of small-pox are the subjects of three reports. Dr. Patrick Manson, of the London School of Tropical Medicine, is one of the reporters. Dr. W. J. R. Simpson, of the London School of Tropical Medicine, is also on the list of reporters, and will deal with the question of organising the teaching of suitable medical treatment for colonists. Other subjects may be introduced, but these are the topics on which printed reports will be issued, if possible before the Congress meets, so that they may be satisfactorily discussed.

For the division of demography a great number of papers are announced. M. Armand Julin, Directeur au Ministère de l'Industrie et du Travail à Bruxelles; Professor Mahaim, à l'Université de Liège; and M. Vilmart, chef de la division d'hygiène de la ville de Bruxelles, are the joint secretaries of this Division. The reports to be presented deal with: (1) the causes of mortality and how they are registered in the different countries; (2) infant mortality and the necessity of uniform statistics; (3) an international nomenclature for the registering of the causes of death; (4) the means which demography affords of foretelling the decrease or increase of population; (5) the best coefficients for the study of the increase or decrease of populations due to marriages, births, and deaths; (6) the theory that the fluctuation in populations depends on the balance between their resources and their requirements; (7) statistics as to urban populations; (8) death-rates according to occupations; (9) how to deal with the spread of insanity; (10) mortality due to alcoholism; (11) migrations, over-population of towns; (12) what are the advantages of special statistics in regard to the poor; (13) statistics and causes of suicides; and (14) inventory and critical study of archives from the demographical point of view. Among the numerous reporters appointed to deal with these 14 different demographical *subjects the only English name* is that of Dr. J. F. W. Tatham, Superintendent of Statistics, General Register Office, Somerset House, London.

It is to be hoped that British sanitary reformers will take a more active part in the work of this Congress than they have done in regard to previous congresses. It is the greatest meeting of the kind held and it has had considerable influence in guiding various legislative assemblies. In any case, there is still time to join and there are few sanitary reformers who would not have something to say on one or more of the above subjects. Papers dealing with other questions should be sent in two months before the opening of the Congress. They may be written in any language, but must have a summary of their contents in French. During the Congress speeches are to be limited to a quarter of an hour and no one is to speak more than twice on the same subject. The executive committee will extract and publish beforehand all such new facts as may be found in these papers which are likely to lead to discussion. Anyone interested in public health questions may become a member of the Congress by applying to the secretary and sending the entrance fee of 25 francs or £1. The wives and daughters of members may, on paying a fee of 10 francs, be admitted to be present at the discussions and excursions without participating in the labours of the Congress. There will, of course, be many excursions and receptions, but the details are not yet settled. Finally there is to be an exhibition of any objects, plans, and drawings that are related to one or more of the subjects which the Congress is to discuss. The exhibitors will not be charged for the space allotted to them, *but they must themselves defray the* cost of the installation of their exhibits.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE *following are some of the* principal amounts, additional to those already announced in THE LANCET, which have been collected for the Fund :—

Looking Back.

FROM

THE LANCET, *SATURDAY*, JUNE 25, 1825.

FOREIGN DEPARTMENT.

ANALYSIS OF FOREIGN MEDICAL JOURNALS.

REVUE MEDICALE—APRIL.

Curious case of the escape of an ear of Barley through the sides of the Chest, about five months after it had been swallowed.

Francis Perron, aged 19, swallowed, towards the latter end of August, 1824, a green ear of barley. This circumstance occasioned no particular uneasiness at the time, and Perron thought nothing more of it. On the 9th of September, however, whilst working at the wharf as usual, he became overheated, and drank a glass of cold water. Four hours after, a very severe pain was felt on the right side, in the vicinity of the seventh and eighth ribs, accompanied with oppression, cough, and sanguineous expectoration. The next morning the symptoms were appeased, but appeared to renew themselves every two days. The man gradually grew worse, and was admitted into the hospital on the 14th of September. At this time the cough was more frequent, but the expectoration less; the respiration, although difficult, sounded well in all parts of the chest: a slight mucous guggle was perceptible, and no sign of *hegophonie* was discoverable; at this time a pricking sensation was felt about the ribs before named, when the cough came on. The pulse was quick and soft, the skin hot, the tongue clean, and the bowels were constipated; a swelling could now be perceived on the right side of the thorax. Frequent general and local bleedings, with a strict antiphlogistic regimen, allayed *these symptoms; but they again appeared on the* 19th and 22nd. The lower part of the chest became prominent toward the convexity of the ribs, and a painful circumscribed tumour was easily detected. The cough continued, and accompanied with a copious mucous expectoration.

27th. Fluctuation in the tumour very perceptible; on pressing on it, the cough, expectoration, and pain, became increased; by continuing the pressure, blood was ejected as in hæmoptysis. The man lay on his left side, and now expectorated a thick puriform fluid with the mucus, communicating a putrescent flavour to the taste. M. LISFRANC was consulted, who considered it imprudent to open the tumour. The application of the stethoscope gave a dull feeble sound in this part, but there was no *tintement metallique.* On the 18th of October, an issue was put on the apex, and on the 25th another at the base of the tumour; it being thought probable, on the eschars coming out, a puncture might be made through one of the wounds, or that the thinness of the covering of the abscess would favour the escape of the matter. This, as was expected, did happen on the 6th of November, but between the two wounds. A large quantity of pus escaped, and the symptoms rapidly subsided. About a month after the first discharge, a new fistula formed, from which there came, on the 30th of December, a longish body of a green colour, about two inches in length, and everywhere covered by a thick mucous plastering.

On the 11th of January, thirteen days after the appearance of the first body, another presented itself quite similar to the preceding, but with the barb, and not the pedicle, foremost. These two substances were immediately recognised, as the blade of the *hordeum murinum*, which had been swallowed five months previously. Perron now grew better, and in a short time was perfectly well. One circumstance was observed, on the discharge of the last piece, worthy of remark—that of the forcible escape of air through the last fistulous opening at each expiration.

This lasted twenty-four hours, and returned only when the man lay on his back, or coughed. Percussion furnished no criterion, on account of the position and the extent of the abscess, *allowing but of its imperfect application.* Many cases have occurred of hard bodies making a passage through different structures; but, as M. BALLY says, "That a green flexible substance, like an ear of barley, should be able, without becoming either altered or bent, to traverse through one half of the thorax, is a phenomenon almost incomprehensible." It is presumed the barley-ear did not separate in two until after the abscess had formed, otherwise it would most probably have effected two distinct passages. The fluid contained in the abscess allowing of the latter piece to change its position, and make its transit at its opposite point.—*Sittings of the Royal Academy of Medicine.*

THE BATTLE OF THE CLUBS.

ON p. 86 of our advertisement columns in this number of THE LANCET will be seen a notice concerning the County of Durham Medical Union. The Friendly Societies Medical Association of Sunderland is now advertising for a second medical officer and we beg that any of our readers who may be thinking of applying for this post will, in the first place, consult either Messrs. Graham and Shepherd, 32, John-street, Sunderland, who are the secretaries of the County of Durham Medical Union, or Mr. Garforth Drury, 55, Pilgrim-street, Newcastle-on-Tyne, who is the secretary of the Northumberland and Newcastle Medical Association. It is most important that medical men should assist medical unions in their efforts to secure increased payments for contract work and that applicants should be made aware of the false position in which they will find themselves should they accept lower rates of pay than those agreed upon by the medical unions in question.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8914 births and 4138 deaths were registered during the week ending June 20th. The annual rate of mortality in these towns, which had been 14·9, 14·3, and 13·9 per 1000 in the three preceding weeks, rose again last week to 14·3 per 1000. In London the death-rate was 13·1 per 1000, while it averaged 14·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 4·7 in Hornsey, 6·2 in Willesden, 6·3 in Handsworth, 6·7 in Tottenham, 7·1 in East Ham, 7·4 in Kings Norton, 7·6 in Ipswich, and 8·0 in Southampton; the highest rates were 19·0 in Sheffield, 19·8 in Grimsby and in Huddersfield, 21·0 in Rotherham, 22·0 in Birkenhead, 23·0 in Middlesbrough, 28·5 in Wigan, and 28·7 in Coventry. The 4138 deaths in these towns last week included 415 which resulted from the principal infectious diseases, against 434, 397, and 404 in the three preceding weeks; of these 415 deaths 136 were referred to measles, 99 to whooping-cough, 73 to diarrhœa, 42 to diphtheria, 38 to scarlet fever, 20 to "fever" (principally enteric), and seven to small-pox. In Hornsey, Southampton, Northampton, Derby, York, South Shields, Gateshead, Newcastle-on-Tyne, and in 10 other smaller towns no death from any of these diseases was registered, while they caused the highest death-rates in Great Yarmouth, Aston Manor, Coventry, Wigan, Oldham, Sheffield, Middlesbrough, and Merthyr Tydvil. The greatest proportional mortality from measles occurred in Wolverhampton, Birmingham, Coventry, Wigan, Sheffield, and Middlesbrough; from scarlet fever in Merthyr Tydvil; from diphtheria in Oldham; from whooping-cough in Birkenhead, Burnley, and Sheffield; and from "fever" in Grimsby. Three fatal cases of small-pox were registered in Oldham, two in Liverpool, one in Manchester, and one in Bradford, but not one in any other of the 76 large towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday last, the 20th inst., was 70, against 60, 72, and 64 on the three preceding Saturdays; 16 new cases were admitted during the week, against 10, 24, and nine in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 1771, 1785, and 1710, at the end of the three preceding weeks had further declined to 1649 at the end of last week; 170 new cases were admitted during the week, against 225, 210, and 145 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 186, 171, and 141 in the three preceding weeks, further declined last week to 134 and were 33 below the number in the corresponding period of last year. The causes of 40, or 1·0 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Bradford, Leeds, and in 50 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, St. Helens, Warrington, Manchester, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·4, 18·2, and 17·5 per 1000 in the three preceding weeks, further declined to 17·0 per 1000 during the week ending June 20th, but was 2·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·7 in Leith and 14·5 in Paisley to 18·2 in Dundee and 20·1 in Perth. The 558 deaths in these towns included 16 which resulted from whooping-cough, 14 from diarrhœa, nine from measles, four from scarlet fever, three from "fever," and one from diphtheria, but not one from small-pox. In all, 47 deaths resulted from these principal infectious diseases last week, against 70, 65, and 49 in the three preceding weeks. These 47 deaths were equal to an annual rate of 1·4 per 1000, which corresponded with the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 28, 25, and 20 in the three preceding weeks, further declined last week to 16, of which eight were registered in Glasgow, four in Edinburgh, and two in Paisley. The deaths from diarrhœa, which had been 18 and 20 in the two preceding weeks, declined again to 14 last week and included 11 in Glasgow. The fatal cases of measles, which had been seven, nine, and three in the three preceding weeks, rose again last week to nine, of which four occurred in Glasgow, three in Edinburgh, and two in Paisley. The deaths from scarlet fever, which had been six, seven, and three in the three preceding weeks, increased again to four last week, and included two in Edinburgh. Of the three fatal cases of "fever" recorded last week, two occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 114, 111, and 75 in the three preceding weeks, further decreased last week to 73, and were 23 below the number in the corresponding period of last year. The causes of 19, or more than 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·2, 22·7, and 22·4 per 1000 in the three preceding weeks, further declined to 19·7 per 1000 during the week ending June 20th. During the past four weeks the death-rate has averaged 21·0 per 1000, the rates during the same period being 13·3 in London and 17·7 in Edinburgh. The 143 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 20 from the number in the preceding week and included 11 which were referred to the principal infectious diseases, against seven, ten, and nine in the three preceding weeks; of these six resulted from whooping-cough, three from small-pox, one from measles, and one from scarlet fever, but not one from diphtheria, from "fever," or from diarrhœa. These 11 deaths were equal to an annual rate of 1·5 per 1000, the death-rates last week from the same diseases being 1·5 in London and 1·6 in Edinburgh. The deaths referred to whooping-cough, which had been two, one, and five in the three preceding weeks, further rose last week to six. The fatal cases of small-pox, which had been three and one in the two preceding weeks, increased again to three last week. The 143 deaths in Dublin last week included 29 of children under one year of age and 26 of persons aged 60 years and upwards; the deaths of infants corresponded with the number in the preceding week, while those of elderly persons showed a marked decline. One inquest case was registered, but no death from violence was recorded; and 57, or almost 40 per cent., of the deaths occurred in institutions. The causes of seven, or nearly 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon C. W. Buchanan-Hamilton to the *Leviathan*. Staff Surgeon A. G. Andrews to the *St. Vincent*. Surgeon T. B. Shaw to the *Hyacinth*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Hughes joins at Aldershot and is posted to the Cambridge Hospital for duty. Captain L. N. Lloyd joins at Aldershot and is posted to the Connaught Hospital for duty. Captain G. Dansey-Browning is posted for duty to the new Princess Louise Hospital at Alton. [illegible] Watson is appointed to the medical [illegible] Margaret Hospital for Women and [illegible]

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Kent: Surgeon-Lieutenant C. M. Anderson resigns his commission. Dated June 20th, 1903. 1st Norfolk: Surgeon-Major S. W. Woollett resigns his commission. Dated June 20th, 1903

Rifle: 3rd Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Captain J. F. Hall resigns his commission. Dated June 20th, 1903. 3rd Volunteer Battalion the East Surrey Regiment: Alfred Landon Watler Whitehouse to be Surgeon-Lieutenant. Dated June 20th, 1903. 3rd Glamorgan: Surgeon-Lieutenant G. A. Stephens to be Surgeon-Captain. Dated June 20th, 1903. 4th Middlesex (West London): Frederic Richard Miller to be Surgeon-Lieutenant. Dated June 20th, 1903.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Woolwich Companies: Captain A. S. Greenway to be Major. Dated June 20th, 1903.

THE WOOLWICH EXPLOSION.

In connexion with the recent deplorable lyddite explosion at the Royal Arsenal, we venture to express a hope that the most liberal interpretation of existing laws and regulations regarding the allowances to be granted to the wives and families of the killed and injured workmen will be given by the War Office, and we are glad to recognise that there seems to be every disposition on the part of the War Minister to act in this spirit. It has to be borne in mind that notwithstanding every precaution that can be taken to guard against accident the workmen who deal with high explosives of a horribly dangerous character run greater hazards in their work than probably fall to the lot of a soldier in war. It is lamentable to think that this nation is driven in times of peace and in order to prepare for war to manufacture such terrible instruments of destruction just because all the other military Powers do so, but so it is. All that can be done in the meantime is to see that no possible precaution is neglected and when accidents do unhappily occur to insure for the victims' wives and families generous and sympathetic treatment.

THE RESULT OF THE COURT-MARTIAL IN THE CAPE RAGGING CASE.

Although those directly concerned in this case may fairly congratulate themselves on the result of the late court-martial, it will nevertheless be held by all, whether military officers or civilians, who have the interest of the army at heart that the sooner it is understood that the King's uniform cannot be permitted to cover conduct of this sort the better. In saying this we are content to form our judgment entirely on the admissions that were made by the officers themselves in their evidence before the court as to what had taken place at Cape Town. The whole transaction was, to say the least, discreditable. We do not hear anything of scandals of this sort in the Royal Navy or in the scientific branches of the military service—the Royal Artillery and the Royal Engineers or in the Royal Army Medical Corps—and it is time that we ceased to hear of them elsewhere.

THE SOMALILAND WAR.

The white man's burden is a heavy and pretty continuous weight in supplying the calls of the Empire. Things have not been going well in Somaliland, where the British troops are in a very awkward position owing to the close proximity of the bulk of the Mullah's forces which are threatening General Manning's line of communication. Some reinforcements have been sent from Aden and others are ordered from India and Major-General Egerton, who has had much and recent experience in Indian warfare, has been nominated for the command in Somaliland. The difficulties of the climate and country are very great, owing to the want of water for one thing and to that of suitable transport for another. The hospital arrangements and supplies will need to be very carefully thought out in order to adapt them to the nature and requirements of such a campaign. These have been engaging the attention of the military medical service in India in connexion with the reinforcements proceeding from that country.

THE ROYAL ARMY MEDICAL CORPS SOUTH AFRICA FUND.

A sum of about £110 remains in the hands of the honorary treasurer, the greater portion of which has been returned from South Africa, being the unexpended balance of an amount sent there for local requirements during the war. With a view to close the fund finally it is proposed to hand over the money to the Compassionate Branch of the Royal Army Medical Corps Fund, lately organised by the Director-General, as it will then be available for cases of need amongst the men, women, and children of the corps. H.R.H. the Princess Christian has graciously signified her approval of the suggestion, which reaches us signed by M. Symonds (honorary treasurer), M. L. Muir (honorary secretary), and H. S. Muir (chairman of the committee). Should no expression of dissent be received from subscribers within the next few days it will be assumed that they concur.

DEATHS IN THE SERVICES.

Inspector-General of Hospitals Michael Waistell Cowan, M.D. Edin., R.N. (retired), at Leigh, near Worcester, on June 20th, aged 72 years. He entered the navy as a surgeon in 1854 and became staff surgeon in 1864, fleet surgeon in 1876, and inspector-general of hospitals in 1888. He retired in 1890. He served in the Black Sea during the Russian war.

Correspondence.

"Audi alteram partem."

ENTERIC FEVER AMONG THE NATIVES OF INDIA AS A SOURCE OF ARMY DISEASE.

To the Editors of THE LANCET.

SIRS,—Those of us who in the years past have recognised the identity of the Indian enteric fever with that existent among other sections of the world's races, regarding it everywhere as a specific disease and, so far as the army is concerned, referring its source of origin as a rule to the native or other communities with which the soldier comes in [illegible] temporary colonies abroad, will find in the [illegible] the Differen- [illegible] of the Tropics [illegible] of May 30th, [illegible] issued Army Medical Report, 1901, p. 160, Enteric Fever among Natives of India, statements which must, I think, remove the doubt existent among some both as to the presence of the disease among the natives of that land and as to the source from which the major part of the army disease derives its existence and place the basis of preventive measures on assured grounds.

A historical sketch of the line of advancing knowledge of this disease in India, culminating in what we may now regard as the recognition of its identity with that elsewhere existent, among natives as among Europeans and half-castes, and owning one common universal cause, though a subject of considerable interest, would cover too much of your valuable space. But as partly elucidatory of the progress of thought and risking the possibility of being regarded egotistical, I may say that in 1882, from my knowledge of the writings of others and from personal observations, I noted[1] that "the existence of the disease in India is beyond the region of doubt and in clinical and post-mortem details at least it follows the

---

[1] Enteric Fever, Illustrated by Army Data at home and abroad, p. 77.

European disease"; that (p. 138) "the specific theory more closely embraces the military data than any other and is the only one which meets the requirements of the facts"; that evidence in support of this conclusion so far as India was concerned was not wanting; and that (p. 193) the "chief obstacle to the view of a derivation of the enteric fever among the military from the civil population rests in a disbelief on the part of some, and a statement of denial on the part of a few, that this disease is one from which the natives of India suffer." Yet even at that time the susceptibility of the native (half-caste also) to the disease, both in his own country and when outside it, was beyond all doubt, the only questions open being the degree to which the disease prevailed, the modifications it possibly assumed, and the period of life during which it was mainly represented among them. It was on these points noted that according to the Annual Health Report of Calcutta for 1880 a considerable amount of fatal fever of a *continued* type existed among natives irrespective of race and that among children under one year of age there were many deaths from "a combination of fever and diarrhœa," and the suggestion was made that the reason why enteric fever was so seldom observed among adults coming under the notice of European medical men was that as in small-pox, so in this disease, an immunity had been purchased by an attack in early life. The means of diagnosis of the Indian fevers now available were not then existent and actual proof of the presence of enteric fever among natives as a common disease was not forthcoming and hence the continuance of doubt, but what was then wanting has now been fully supplied by the application of Widal's test to the blood. Some years ago Surgeon-Major Freyer of the Army Medical Service brought forward some results of the application of this method to the blood of adult natives in which the outcome of his observations suggested a prior attack of the disease as a possible and probable explanation, and the publication referred to in the early part of this letter may, I take it, be regarded as conclusive of the subject under consideration. Captain Rogers (p. 1504) writes: "The above brief summary is sufficient to prove that typhoid fever is a common continued fever of the natives of India and that it differs in no noteworthy respect from the same disease in Europeans in this country," and (p. 1508) "the so-called 'non-malarial remittent' fever in natives has been shown by the serum test to be nothing but typhoid fever." And the notice in the Army Medical Report, 1901 (p. 160), is: "It is now generally admitted not only that enteric fever does attack natives of India but that cases are by no means of such rare occurrence as was at one time supposed. At Kirkee seven natives were treated for the disease during the year in the native section of the station hospital, the diagnosis in each case being verified by Widal's test. At Peshawur, during the time that enteric fever was most prevalent among the troops, there were several suspicious deaths from fevers in the Royal Artillery and Light Infantry Bazaars, and at Quetta cases resembling enteric fever occurred among natives just before the disease broke out in barracks. In the Barrackpore report the occurrence of enteric fever among the native population is put forward as an explanation of isolated cases among the troops." And, indeed, so far as the last sentence is concerned this is the view taken and enunciated by some of us for the last 20 years at least.

Hence, then, the view taken by your reviewer of the Report of the Sanitary Commissioner with the Government of India for 1897 in THE LANCET of August 19th, 1899, p. 495, that, assuming enteric fever to be a parasitic disease, "the bacillus must be very widely distributed in India," and to which I replied in a letter to you[2] giving details tending to meet that requirement, is confirmed beyond all reasonable doubt, and now I presume that we may all settle down in the conviction that enteric fever, wherever met with and in whatever race, is one and the same disease and that, so far as the army is concerned, the source of its disease, putting aside occasional importation and occasional transfer in its own coterie, is everywhere the civil and native community of the country in which it is quartered, and that the means for its curtailment (the idea of elimination not being reasonable under the conditions which exist) are to be sought in the reduction of the very susceptible human material sent out to India and elsewhere and the safeguarding as far as possible of the lines of communication between the native and military sections.—I am, Sirs, yours faithfully,

FRANCIS H. WELCH,
Surgeon-Colonel (retired), A M S.

Lee, June 15th, 1903.

THE IMPERIAL VACCINATION LEAGUE.

To the Editors of THE LANCET.

SIRS,—The Imperial Vaccination League has now been in existence for a year. It has had in view two objects: first, to study the working of the Vaccination Act of 1898 in order to consider if in any way the Act or its administration can be improved and the opposition to vaccination diminished; and, secondly, to press upon the attention of all classes of the community the immense value of vaccination and revaccination as a protection against epidemic small-pox The league has so far been mainly occupied in making a critical study of the Vaccination Act of 1898. As a result of this study it recommends the general compulsory revaccination of children before leaving school; the extension of the conscience clause to revaccination as well as to primary vaccination; the transference of the vaccination laws from the Poor-law to some other authority charged with public health functions; that the same security of tenure be given to the public vaccinator as is now enjoyed by the vaccination officer; and that all establishments for the preparation in England of calf lymph be placed under Government inspection or control. The league does not approach the subject of the administration of the Vaccination Act from the point of view of the interests of the medical profession or of the public vaccinators. It inquires only what will best promote vaccination among those sections of society now prejudiced against it. Should it appear on investigation that the cost of vaccination under the Act of 1898 has been in some cases unreasonably great the league would favour its being reduced. It believes it to be of the utmost importance that the medical profession should be moderate in its pecuniary demands, that nothing should be done to make martyrs of anti-vaccinationists, and that vaccination and revaccination should be efficient as well as obligatory.

The league was formally constituted at a large and influential meeting of its members, over which the Duke of Northumberland presided, on Dec. 12th, 1902. On Jan. 14th, 1903, a deputation representing merchants, bankers, shipowners, large employers of labour, municipal authorities, dockyard companies, heads of public schools and colleges, solicitors, insurance companies, sanitary authorities, the Royal Colleges of Physicians and Surgeons, wharfingers, traders, givers of concerts and influential persons generally, waited on the Right Hon. Walter Long, M.P., President of the Local Government Board, to urge upon him the importance of making revaccination obligatory before the legal age for employment and of providing an adequate supply of glycerinated calf lymph available for all classes of the community. Many sheets of signatures of influential persons in support of obligatory revaccination were handed to Mr. Long by members of the deputation. The President, in reply, urged the league to extend its work into the country, and especially to assist candidates at Parliamentary elections to meet the pressure put upon them by the opponents of vaccination. The league desires to act upon Mr. Long's advice. It has recently issued a paper entitled, "Ten Answers to Questions on the Subject of Vaccination for the Use of Parliamentary Candidates" which can be had from the Secretary of the Imperial Vaccination League, 53, Berners street, London, W. A political secretary (Dr. Rees Roberts) has been appointed whose duty it will be to attend Parliamentary elections and to form local committees in defence of vaccination. For this extension of the work of the league an additional sum of £500 a year for three years will be required. The executive committee desires to find 100 friends who will each promise five guineas a year for three years, or a larger number who will make up the amount wanted in smaller sums. It is not probable that the effort to produce a Revaccination Act need last much more than three years. Such an Act can be passed within that time if the Government a country desire it. If, on the other hand, people d prefer frequent epidemics of small-pox to vaccin must have their own way and take the consequen while the league will do what is possible majority to other and more social views. Subscriptions or donations to the funds of the league may be sent by crossed cheque to the Secretary, Imperial Vaccination League, 53, Berners street, London, W., or to myself.

---

[2] THE LANCET, Sept. 9th, 1899, p. 739.

I am, Sirs, yours faithfully,
E. GARRETT ANDERSON,
Honorary Secretary, Imperial Vaccination League.
4, Upper Berkeley-street, London, W., June 20th, 1903.

BLOOD PRESSURE.

To the Editors of THE LANCET.

SIRS,—I have to thank your correspondent Dr. O. P. White, writing in THE LANCET of June 20th, p. 1767, for a correction—the term "cubic" having unfortunately crept into the type-written copy of my address[1] in connexion with millimetres of mercury pressure, that term being, as he says, the measure of volume. With regard to Dr. White's reference to the diminution of the partial pressure of the oxygen in the higher altitudes being possibly the cause of the rise in blood pressure, it may, I think, be an important factor in the background as it were; but I am disposed to think that other causes are at work. My conclusions were strictly limited to the data observed, which pointed to the proximate causes of the rise. I am satisfied that the primary effect of altitude is to lower the arterial pressure and that in winter this effect is apparent in the medium altitudes; but that in the higher altitudes other factors of causation step in which raise the pressure It is possible, for instance, that temperature is one of these. The whole subject requires further investigation. When the Yungfrau railway is extended to 13,366 feet a good opportunity for this inquiry will be afforded, inasmuch as the railway carriage will provide the important conditions of rest and equable temperature. The interesting paper of Dr. Theodore Zangger in your issue of this week shows the necessity for such an inquiry and I am looking forward to an opportunity of doing further work in this direction. Dr. White mentions the increased pulse-rate in balloon ascents up to the height of 24,000 feet, which is interesting, but may not the psychological element in ballooning somewhat impair the reliability of any conclusion as to the effect of altitude on the pulse-rate?

I am, Sirs, yours faithfully,
GEORGE OLIVER, M D., F.R.C.P. Lond.
Harrogate, June 20th, 1903.

SYPHILIS—A QUESTION OF PROCEDURE.

To the Editors of THE LANCET.

SIRS,—I should very much like to know what is the proper course of procedure in the following case.

A patient is seen at the out-patient department of a hospital and is found to have secondary syphilis with ulcerations of tonsils, lips, &c. He states that he is a baker's assistant and that whilst not handling the dough *he handles the baked loaves just prior to their being sent out for consumption.* On being told that he must not continue this work he refuses, saying that he cannot afford to give up his "job"

What course should I adopt? 1. Should I write to his employer? If in this case he is dismissed, do I render myself liable for damages in a court of law? 2 Should I communicate with the medical officer of health of the district? And if he is subsequently dismissed owing to this officer's action, do I still render myself liable? 3 Should I take no notice and allow this filthy state of things to continue?

I am, Sirs, yours faithfully,
J. GAY FRENCH, M.B. Lond., M.R.C.S. Eng.,
L.R.C.P. Lond.
June 22nd, 1903.

⁂ 1. The employer cannot be written to without a breach of professional confidence. But the breach would, we think, be pardonable. It is a complete answer to any civil proceedings for libel or slander that the statement complained of is true, and to any criminal proceedings that it has been made in the public interest. 2. The medical officer of health might be communicated with but his power of interference is not evident to us as syphilis is not a notifiable disease. 3. We think that a distinct warning might be given to the unfortunate sufferer that unless he desists from his work until he is no longer infectious his plight must be revealed to his employer—a threat, the legality of which is perhaps doubtful. Dr. French should ascertain the views of the hospital authorities. This is important.—ED. L.

APPENDICITIS: A SUGGESTED REASON FOR ITS INCREASE.

To the Editors of THE LANCET.

SIRS,—The occurrence at the same time in one's own private practice of three cases of appendicitis, each demanding operation, is provocative of thought. Ten years ago cases of "perityphlitis" came under notice occasionally and a certain number of people were taken ill and died from "inflammation of the bowels" or "acute peritonitis" in whom an appendicitis was probably at the root of the mischief. My recollection is that such cases were rare and I do not remember one appendicectomy at the Royal Infirmary, Liverpool, *during my period of studentship*, 1887–91. At the present time appendicitis is about us on every hand. The reason for its sudden increase has yet to be shown. I do not believe it to be due to any process of evolution; the same people are having appendicitis now who did not have it ten years ago. The cause, whatever it is, must be one affecting the mass of the people, rich and poor; it must be common to all countries of high civilisation and big towns; it must be coincident with the increase in the disease.

The present conditions of food supply and distribution may give the key to the situation. Probably four-fifths of the chief perishable comestibles are frozen or chilled for transmission or collection before reaching the consumer. Chilled or frozen meat, fish, poultry, rabbits, game, &c., are notoriously prone to rapid decomposition when removed from cold store; also, they degenerate more rapidly after cooking than unfrozen articles. Following the argument it may be that the ingestion of chilled or frozen food especially liable to rapid decomposition may result in a more septic state of the intestine than in the pre-cold storage days, and this greater septicity may in its turn account for the greater virulence of those irritations to which the cæcum and appendix have always been prone.

I am, Sirs, yours faithfully,
S. KELLETT SMITH, F.R.C.S. Eng.
Liverpool, June 22nd, 1903.

THE GENERAL MEDICAL COUNCIL AND THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—The letter of Dr. R. W. C. Pierce in THE LANCET of June 20th, p. 1768, is interesting as evidence of a "reversal of policy" on the part of the Colleges. This is to be expected. The increasing number of universities in the provinces and the establishment of facilities for obtaining medical degrees in London tend to diminish the demand for the Conjoint diploma, for no man will take a diploma when he has reasonable facilities for taking a degree, provided the respective standards nearly approximate. It is on these grounds that the Colleges should, I submit, be merged into the University of London, for though the Colleges have done good work in the past the days of the diploma are quickly passing by.

I am, Sirs, yours faithfully,
Brighton, June 20th, 1903. FREDK. W. COLLINGWOOD.

MOLYNEUX'S PROBLEM.

To the Editors of THE LANCET.

SIRS,—Dr. A. M. Ramsay's report of the case of a Man Blind from Congenital Cataract who Acquired Sight after an Operation when he was 30 years of age, given in THE LANCET of May 16th, p. 1354, is of extreme interest to students of psychology. There is one point on which further explanation would be welcomed. Dr. Ramsay says: "When asked to distinguish between a ball and a toy brick he looked at them for a considerable time ...... and then he described both correctly." It cannot be meant that he said: "This is a sphere and that is a rectangular parallelopiped," or something equivalent. Even with normal eyes and lifelong experience it is not possible to see a sphere as a sphere or a cube as a cube. Molyneux, in stating his famous problem, supposed, as I understand him, that the patient was told that one of the bodies shown him was a cube and the other a sphere and was only asked to say which was the cube and which was the sphere. Was it in this way that Dr. Ramsay's patient was tested? Even Dr. Franz's patient, whose case is so carefully reported in the Philosophical Transactions for 1841, does not seem to have been tested in this way, although we may perhaps conjecture what the result would have been from the fact that he said he saw the cube as a quadrangular figure and the ball as a disc. If Dr. Ramsay's patient was simply asked to say which was the ball and which was the brick this would, I believe, be the first case in which Molyneux's problem was tried as he stated it.

---

[1] THE LANCET, June 13th, 1903, p. 1645.

I am, Sirs, yours faithfully,

Trinity College, Dublin, June 22nd, 1903. T. K. ABBOTT.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Legacies to Local Charities.

Mr. Thomas Best, the survivor of two brothers who had for many years carried on a successful manufacturing business in this city, has bequeathed his entire fortune, amounting to over £100,000, to various charitable objects. The destination of about half this sum was decided by the will, the other half being left in trust to the Lord Mayor and corporation, in order that they may invest it and apply the annual income for the purposes of institutions in Birmingham and the Midland counties supported, at least in part, by public subscriptions. The specified moiety goes to various institutions in the city, the more important bequests to hospitals being £5000 each to the General Hospital and the General Dispensary, £4000 each to the Blind and Deaf and Dumb Institutions, £3000 to the Queen's Hospital, £2000 each to the Children's, Women's, and Orthopædic Hospitals, and £1000 each to the Eye and Ear and Throat Hospitals. Mr. Best was no doubt justified in trusting the disposition of one half of his fortune to the discretion of others, but that such a method of dealing with one's worldly goods may sometimes be a doubtful policy is illustrated by another series of gifts which have recently been made public. Dr. Griffiths of Washwood Heath, who recently died, had been for many years a well-known and much respected general practitioner in the eastern division of the city and one of the members of the corporation. Instead of deciding for himself as to the objects to which his money should be devoted he left the disposition of it to trustees. It must be confessed that it is difficult to suppose that the late medical gentleman would have approved of some of the objects to which his money has been devoted by those in whose hands he placed its distribution. It seems unlikely that he would have selected the Homœopathic Hospital as the recipient of £200, nor, considering the feelings entertained towards the General Dispensary by general practitioners, can one suppose that he would have selected that institution as one which should benefit by his generosity to the tune of £100. Finally, a similar sum given to the University is to be applied to the purchase of books for the department of English literature, though the medical school has many crying necessities, towards the satisfaction of which a gift of such a sum would have been very acceptable. The way in which this money has been distributed will perhaps give pause to medical men contemplating a similar method of disposing of their wealth after their death.

Medical Benevolent Society.

The eighty-first annual meeting of this society was held on May 29th, when Mr. M. A. Messiter of Dudley was elected President and Dr. E. Malins President-elect. It was announced that the invested funds of the society amounted to £15,688 4*s.* 6*d.*, that there were 414 members on the books, and that a sum of £659 had been expended during the year in grants and Christmas donations. To the sum mentioned above will have to be added an amount of £5000, less legacy

interests. When it comes into the possession of the soc this sum of money is to be invested and called "the Duncal Benevolent Fund."

Hospital Saturday Fund.

Saturday, June 13th, was the day set aside for the annu collection for this fund. The full amount has not yet bee received but it will obviously be larger than in any previo year. As on former occasions Alderman Cook, the chai man of the executive committee, entertained the membe of that body to tea after the conclusion of their labours f the day. In the speech which he made on that occasion th alderman congratulated the committee on the fact that th prospects of raising the £20,000 which they desired we very bright. No less a sum than £278,855 had been receive from the citizens in connexion with the fund during th last 30 years—a truly wonderful record. He desired to s the time when it would be possible to establish a sanatoriu for consumptives under the auspices of the fund. Such institution was greatly needed and when its establishme was possible he was confident that the Hospital Saturda executive would be able to carry on the work as well as an other body in Birmingham. The Lord Mayor in his spee strongly supported the suggestion that such a sanatoriu should be started for the use of the working classes of th city.

Crippled Children.

A conference on the subject of the welfare of crippl children has just been held at the Women's Settlement i this city. It was presided over by Miss Dale, one of th members of the education committee of the city, and the were present representatives of nearly all the organisatio in the country for the care of crippled children. Before th reading of papers most of the delegates visited the speci school maintained by the education committee for this cla of children and were shown the ambulance which conve the scholars from their homes to the school which is situate in Dean-street. In a paper by Miss Fisher of the Manchest University Settlement it was stated that the actual numb of cripples in the country was not known, but that M Knipe, honorary secretary of the National Industrial Hom for Crippled Boys, estimated the number in 1888 as 100,00 In Birmingham there were 537 crippled children known t the union. Dr. F. Warner estimated that three in ever 1000 of the children attending public elementary schools i London were maimed, crippled, or deformed. Accurat figures about those who were unable to attend school we unobtainable. As to the nature of the disablement, mor than half of the cases were due to hip, spine, and other bon diseases; infantile paralysis came next, and then ricket amputations, and deformity. In many cases a slight inju was aggravated by carelessness and neglect or by a mi taken kindness which prevented parents from taking the crippled children to a hospital.

Deaf and Dumb Institution.

The annual meeting of the friends of this charity ha recently been held under the presidency of the Lord Mayo There had been no recurrence of the epidemic of scarlet fev which had visited the institution in the previous year. Th committee had again found it necessary to appropriate £5 from the legacy fund towards meeting the year's deficienc of ordinary income, which amounted to over £1000.

Hospital for Women.

A sum of £320 has been handed over to the committee o this hospital by the Master Bakers and Millers' Associ tion as the result of a football match and sports hel in May last in the grounds of the Aston Villa Footba Club. At the annual meeting of the committee responsib for the church parade and service held each year for th benefit of the Women's Hospital by the Sparbrook and Di trict Amalgamated Friendly Societies the chairman me tioned that last year £260 were raised for the hospital an expressed the hope that this year the contribution would n be less than £300. Councillor Nettlefold said that designing the new hospital the committee started with high ideal because it felt that if it did not aim at moon it would hit nothing worth having. Whilst it strive for one of the best hos [illegible] its kind in the Kingdom the committee di [illegible] to be a replete with all sorts of fa ago its policy of inq meeting of the hospital committee that £29,325 had been raised towards the £30,000 which it had determined to raise before starting upon the work of the building. The new hospital would, however, cost £40,000, and he wished that the committee could have collected the entire sum before commencing operations.

Queen Victoria Nursing Institution, Wolverhampton.

The annual report of this charity shows that the present staff consists of 30 fully trained medical and surgical nurses, who have during the year attended 255 cases under 92 medical men. During the year 91 operations have been performed and altogether 107 patients have been admitted—an increase of 50 on the previous year. Increased accommodation has been provided at the institution by the addition of another room. A resident assistant to the lady superintendent has been appointed on account of the great increase in the work of this official. The district home has been removed to Waterloo-road, South, but regret is expressed that the appeal for increased subscriptions for this part of the work has not met with an adequate response The statement of accounts shows that, including the balance in hand, the receipts have amounted to £2346, including £1273 as fees for nursing. The balance in hand amounts to £263 The report with regard to the District Nurses' Home shows that 1074 cases were attended during the past year and that he nurses paid 21,681 visits.

June 23rd,

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Late Dr. J. B. Nevins.

THE late Dr. Nevins, who died on June 10th, at the venerble age of 84 years, was one of the most estimable citizens f Liverpool and had been for many years a leader of ntellectual thought in the city. His literary achievements ere of the highest order. His habits of life conduced to is acquiring knowledge. He was a busy worker all his ife. He was twice president of the Literary and Philoophical Society of Liverpool, firstly from 1869–72 and econdly from 1894–96. He was elected president of the iverpool Medical Institution in 1886, an office which he illed with credit for two years. He took an enthusiastic nterest in all public questions and there were few benevolent r philanthropic institutions in the city with which he was ot associated. Up to a recent period he was to be seen lmost daily in the streets, his brisk walk and alert anner showing few traces of his great age. An attack f influenza, aggravated by a weak heart, compelled him o take to bed a few weeks ago, and he gradually sucumbed. His funeral, which took place on June 13th, was ttended by a large concourse of citizens of all shades of pinion, including members of philanthropic, literary, and cientific societies, the medical profession being largely epresented.

The Anatomical Society of Great Britain and Ireland.

The annual summer meeting of this society took place on June 19th and 20th at University College, Mr. C. B. Lockwood (London) presiding. Amongst those present were Principal Sir William Turner, K.C.B. (Edinburgh), Sir W. M. Banks (Liverpool), Professor D. J. Cunningham (Edinburgh), Professor H. Young (Manchester), Professor G. D. Thane (London), Professor J. Symington (Belfast), and Professor A. Robinson. Professor Robinson contributed an interesting paper on the Development of the Cranial Form in Man. He described experiments showing that the form of the skull was closely associated with the size and leverage of the lower jaw. Professor Symington gave a demonstration on the Relation of the Deeper Parts of the Brain to its Surface. The annual dinner of the society took place at the Adelphi Hotel on the evening of June 19th, when some 40 members were present.

Continued Abatement of the Small-pox Epidemic in Liverpool.

29 new cases of small-pox were notified to the health authorities during the week ending June 18th, which showed a marked decrease on previous weeks. There were 165 cases in hospital at the same date, as compared with 198 on June 4th and 335 on March 19th, showing a decrease of 50 per cent. in the number of cases in hospital at the end of the quarter.

Lectures on Tropical Ophthalmology.

Major H. Herbert, I.M.S., professor of ophthalmic medicine and surgery, Grant Medical College, Bombay, delivered two lectures to the students of the Liverpool School of Tropical Medicine in the lecture-room of the Thompson-Yates Laboratory on June 18th and 19th on Some Special Points in Tropical Ophthalmology. The lectures were highly interesting and were much appreciated by a large audience.

Birkenhead Children's Hospital.

The High Sheriff of Cheshire, Mr. T. B. Royden, opened the new wing recently added to the Birkenhead and Wirral Children's Hospital on June 12th, in the presence of a company which included the Bishop of Chester, the Bishop of Shrewsbury, the Mayor and Mayoress of Birkenhead (Dr. and Mrs. R. Owen Morris), and others. The chairman of the hospital (Mr. J. Elliot) sketched the growth of the hos-

for the shelter of perambulators; on the first floor there are five bedrooms, a dining-room, bath-room, &c.; and on the second floor five more bedrooms, &c. This accommodation is for the nursing staff who have hitherto been much cramped in the main building through want of space. The building and furniture have cost £3360, of which £650 have yet to be found. Last year the hospital admitted 540 patients, and there were 6234 out-patients.

June 23rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

University of Wales.

Dr. Andrew Francis Dixon, who has been during the past six years professor of anatomy and dean of the faculty of medicine at University College, Cardiff, has been elected to the chair of anatomy, Trinity College, Dublin, in succession to Professor D. J. Cunningham. The Cardiff School of Medicine loses a most capable administrator through the resignation of Professor Dixon.—Mr. K. J. V. Orton, M.A., F.C.S., assistant lecturer on chemistry at St. Bartholomew's Hospital Medical School, has been appointed professor of chemistry to the Bangor College of the University of Wales.

Appointment of Colliery Surgeon at Maerdy.

The final ballot of the men working at the Maerdy collieries in the Rhondda valleys for the election of a surgeon to succeed the late Dr. Benjamin Griffiths has resulted in the appointment of Dr S. Glanville Morris of Nantgaredig,
